While the total dollar amount of fraud may be a daunting figure, it only accounts for the total amount that has been reported. Some individuals and organizations do not report losses for several reasons (underreporting to shareholders, embarrassment, and not knowing fraud is being committed); therefore, the actual figures may be much higher than the reports shown. Irrespective of those who fail to report, what the trending data reveals of those known losses is that the number of fraud schemes and losses is growing, becoming more complex, and they are responsible for approximately 5% of organization losses annually (Association of Certified Fraud Examiners 2018). Bank fraud, in particular, has become an ever-growing problem for federal and state law enforcement and private sector investigators to combat due to the complexity of the types of schemes being perpetrated. The schemes in question are a by-product of a growing problem of identity theft and cybercrime. These complex relationships, in turn, have required financial industries, in conjunction with federal, state, local, and private investigative sectors to continually employ methods to keep up with those schemes.

For example, according to a 2018 fraud report from Javelin Strategy & Research, the increases and complexities of the schemes from 2016 to 2017 in the USA have revealed a 120% increase in the number of card-not-present fraud schemes, which is when transactions are made online or via a phone where the physical card is not required to complete the purchase. The rise of card-not-present schemes appeared to coincide with the new regulations requiring EMV technology to be used on credit and debit cards, thus making it more difficult for criminals to make in-store purchases with counterfeit credit or debit cards. Criminals, in response to the rise of EMV technology, have resorted to making online purchases. In this example, investigators must work with merchants and financial institutions to find ways to address this type of fraud.

While the schemes have increased in complexity, the victims of those schemes have remained constant, as have the federal and state criminal codes. At the federal level, the bank fraud criminal code addresses any act or throughway (Internet, wire fraud; snail mail, mail fraud) in which one either attempts or successfully completes the criminal act. It can be a single charge comprising several offenses such as forging or using counterfeit financial documents, embezzlement, falsifying information on financial applications, check kiting, forgery and altered checks, using or producing counterfeit or altered access devices, and mail fraud. Bank fraud can also be charged in conjunction with any of the previous noted offenses. For instance, you can have a single bank fraud charge and a single charge of credit card fraud and wire fraud. It is oftentimes an element of a cyber theft in which a computer is used to further crimes such as embezzlement, fraud, and theft of financial data.

While there are many offenses that can constitute a single bank fraud charge at the

federal level, bank fraud, at the state level does not, in most cases, have a single bank fraud criminal offense. Rather, most states have dozens of statutes addressing the various offenses. Therefore, there is no single "bank fraud" state charge that was found; instead, there are a variety of infractions that on its own constitute a crime against a financial institution. For instance, in New York State, a wide range of fraud offenses, such as issuing a bad check, forgery, fraud in solvency, and fraud involving a security interest, can fit within the "bank fraud" category (Article 190-New York State Penal Code 2018). Likewise, in California and Texas, there are also a variety of offenses that fall into the bank fraud category. In California, there are check fraud; credit card, debit card, and access card fraud; and forgery and bad check charges that fall under the "bank fraud" category (Penal Code 470 PC, California's Forgery Law 2018). Likewise, in Texas, there are also many forgery laws that fall under the bank fraud category such as forgery, credit card or debit card abuse, false statement to obtain property or credit or in the provision of certain services, credit card transaction record laundering, and misapplication of fiduciary property or property of financial institution (Texas Penal Code – Chapter 32-Fraud 2018). Although each state may have different codes and processes used to prosecute these offenses, the common denominator between them is their use in prosecuting fraud committed against financial institutions.

Terms

Access device – means any card, plate, code, and account number that can be used, alone or in conjunction with another access device, to obtain money, goods, services, or any other thing of value or that can be used to initiate a transfer of funds (other than a transfer originated solely by a paper instrument).

Bank fraud – the criminal act that occurs when a person or persons uses illegal means to receive or attempt to receive money or assets from a bank or other financial institution. This definition includes fraud by falsely posing as a financial institution.

Check kiting – a type of check fraud in which an individual takes advantage of "the float" to make use of nonexistent funds in a checking or bank account. The float is duplicate money found in a bank account during the time between a deposit being made into the recipient's account and debited from the sender's account.

Counterfeit access device – means any access device that is counterfeit, fictitious, altered, or forged or an identifiable component of an access device or a counterfeit access device.

Credit card fraud – any theft or fraud committed or attempted involving a payment card.

Dumpster diving – the act of digging through a trashcan or dumpster to obtain personal or business documents that contain PII or financial data.

EMV technology – named after the companies that first developed and implemented the technology (Europay, MasterCard, and Visa), this type of technology has a microchip embedded in the card that stores and protects the cardholders' data. The EMV replaces the need for the magnetic strip on the back of the credit/debit card, which is less secure.

Federal Deposit Insurance Corporation (FDIC) – is an independent agency created by Congress in 1933, as part of the 1933 Banking Act during the Great Depression to restore trust in the US banking industry. The FDIC initially insured up to $2500, but now it insures up to $250,000 in assets.

Financial institution – is defined by federal law to include banks and credit unions that are federally insured, such as by the Federal Deposit Insurance Corporation (FDIC), Federal Reserve banks, mortgage lending businesses, and certain other institutions that accept deposits of money and other assets.

Forgery – is the making of a fake document, the modification of an existing document, or the unauthorized signing of a signature without prior authorization.

Fraud – deception intended to result in financial or personal gain.

Identity fraud – the use of one person's identification by another without prior authorization involving fraud or deception.

Mail fraud – any fraudulent scheme perpetrated via mail services.

Mail theft – when an individual(s) removes mail that may contain PII, credit card information, or bank statements.

Personally identifiable information (PII) – any personal information that could be used to identify a specific person and distinguish one person from another. Common PII data can be found in one's Social Security Card, birth certificate, personal check, or driver's license.

Scheme – make plans, especially in a devious way or with intent to do something illegal or wrong.

Securities Investor Protection Corporation (SIPC) – was mandated by Congress in 1970, as part of the Securities Investor Protection Act (SPIA). SIPC covers up to the first $500,000 invested in stocks or money market accounts.

Shoulder surfing – the act of spying on someone using an ATM or other devices in an attempt to obtain PII or access and personal financial data.

Skimming – this can occur at restaurants, ATM's, gas stations, or other types of venues that are heavily trafficked. Criminal instruments known as skimming devices can be as small as a handheld swiped device, or it can be affixed to the front of an ATM or a gas pump where customers insert their credit or debit cards. The skimming devices, which are readily available online, capture the relevant information embedded within the credit or debit cards (credit card number, name, and CVC number) which is then either downloaded via USB or wirelessly transferred where it can then be embedded onto a "white card," a counterfeit credit or debit card, or stored to make illicit online transactions. In most instances, the victim doesn't know their information has been stolen until they start receiving statements showing the illicit transactions or if they see their bank accounts have been compromised.

Social engineering – when an individual, in person, over the telephone, or by computer, deceives an individual into divulging their PII and other sensitive information.

White collar crime – financially motivated, nonviolent crime usually associated business and government professionals.

Wire fraud – any fraudulent scheme perpetrated via Internet or wired services.

Who

Who: Part I – The Criminal Element

The types of individuals who commit bank fraud are as diverse as the schemes themselves. They range from the individual lone actor who might be a bank employee or a waiter at the local restaurant to a cyber-criminal organization that operates online and has a vast amount of technical expertise at hacking into databases and evading law enforcement technical experts. The criminal element has remained an essentially faceless group who have used their technological skills to collaborate in schemes from across the globe, while using cyberspace to remain anonymous.

Despite their ability to remain anonymous, law enforcement groups have made inroads into the various types of criminal groups and their general regional bases of operations. According to a report titled *The New Mafia: Gangs and Vigilantes*-A Guide to Cybercrime for CEOs (Malwarebytes 2017), cybercriminals can be divided into four groups: traditional gangs, state-sponsored attackers, ideological hackers, and hackers for hire. Two of the more relevant gang types to this entry are the traditional and state-sponsored gangs. Traditional gangs have the same goal in mind as their drug and crime gang counterparts, to obtain as much money as possible, as quickly as possible. In many instances, these traditional cybercrime gangs are the same individuals connected to traditional drug and crime organizations, who band together as experienced hackers and attempt to use their expertise to attack and disrupt individuals and organizations via the Internet. State-sponsored gangs have received a lot of recognition lately, with the investigations into Russian government sponsored interference in the 2016 US Presidential election. Before then, state-sponsored hackers from Russia, North Korea, and China were primarily thought to be the primary actors perpetrating data breaches and phishing schemes. Although they are often times credited

with international espionage incidences, they are beginning to participate in corporate theft and sabotage (Malwarebytes 2017).

In regard to bank fraud schemes in particular, a look at the FBI's Top 5 Most Wanted for Cybercrimes reveals four Russian (4) and a group of seven (7) Iranians wanted for a variety of bank fraud and data breach schemes (Park 2017). Similar to the FBI's Cybercrimes list, law enforcements groups have placed the larger cybercriminal operations in Russia, China, and North Korea. Individually, however, anyone in any location can their computer to capture PII and financial data.

Who: Part II – Law Enforcement

There is some confusion about which law enforcement agency is the primary agency responsible for investigating bank fraud offenses. The reason for this confusion is twofold: The first is because both the US Secret Service and the Federal Bureau of Investigations (FBI) investigate bank fraud, sometimes individually, sometimes jointly, and sometimes as members of Financial Fraud Task Forces. The second reason for the confusion stems from the types of bank fraud for which each is responsible.

The Secret Service, initially created in 1865, as an investigative division within the Department of Treasury took on the tasks of investigating rampant counterfeiting following the Civil War, Klan activity, and bank robbery. While it is primarily known as the agency that provides protection for the president and vice president, it wasn't until the assignation of President William McKinley in 1901 that it began carrying out those tasks. Secret Service duties expanded even further with the passage of the Comprehensive Crime Control Act of 1984, which expanded its jurisdiction to include identity fraud (18 US Code 1028), credit card fraud (18 US Code 1029), and computer fraud (18 USC 1030). The Secret Service has also established a Financial Crimes Task Force (FCTF) comprised of state, local, and federal law enforcement agencies, as well as private entities, to encourage interagency and private sector collaboration on financial crimes investigations, as well as a Cybercrime Task Force (ECTF) to investigate cybercrime.

While its initial mission did not start out as diverse as that of the US Secret Service, the FBI was created in 1908 by US Attorney General Charles J. Bonaparte, as a "regular force of special agents available to investigate certain cases of the Department of Justice (White-Collar Crime 2016)." The difference in the types of bank fraud cases they work, which differs from the Secret Service, is that the FBI targets "sophisticated, multi-layered fraud cases that harm the economy (White-Collar Crime 2016)." Therefore, its major focus is on crimes such as corporate fraud, securities and exchange fraud, mortgage fraud, and money laundering. The FBI also has its own Financial Fraud Enforcement Task Force that works with its federal partners and local agencies to investigate large-scale criminal enterprises (White-Collar Crime 2016).

To accomplish their missions, the FBI and Secret Service both work closely with the Securities and Exchange Commission, the Internal Revenue Service, the US Postal Inspection Service, the Commodity Futures Trading Commission, and the Treasury Department's Financial Crimes Enforcement Network, as well as state and local law enforcement agencies (White-Collar Crime 2016).

What

Schemes: What Are the Criminals Doing?

As outlined in the Introduction, there are times when investigators are unaware of specifics other than the fact that some suspicious activity has occurred or is occurring. Similar to the Sherlock Holmes quote above this heading, investigators must work the case backward in an effort to determine what has happened and how it has happened. What is known in general is that the criminal element is trying to find as much PII and financial date as possible so they can convert that data into cash or goods. How they accomplish this is by looking for and developing avenues upon which to prey on technical and nontechnical vulnerabilities.

Technical vulnerabilities can come in the form of computer and Internet avenues, (data breaches, phishing, malware social engineering schemes), otherwise, known as cybercrime. According to the US Secret Service, "evidence in criminal investigations is often scattered across numerous domestic and international jurisdictions, and may be held by a wide range of technology providers and digital devices (The Investigative Mission 2018)." The digital devices previously noted come in the form of small handheld scanners or computer devices used in skimming and jackpotting schemes. Nontechnical vulnerabilities can be described as acts such as shoulder surfing, mail theft, and dumpster diving.

Some of the methods used by criminals to collect PII and financial data rely on a combination of both technical and nontechnical vulnerabilities. An insider threat is a vulnerability that can straddle both the technical and nontechnical variables, as you can have a person working for a merchant or financial institution, for example, who uses their position to obtain the PII or financial data of customers and then use that information to commit various bank fraud crimes themselves or as part of a criminal enterprise. Irrespective of how the data is collected, criminals are quickly able to put that data to work, to illicit as much cash, in as quickly a time frame as possible.

The following list of schemes are some examples of the types of methods used by the criminal element to gather and then use PII and financial data. In many of these examples, the schemes identified are the second offenses committed, with the first being identity theft. For instance, an individual can be a victim of identity theft, which will then lead to criminals obtaining credit cards in the victim's name, submitting fraudulent loan applications, or opening new checking accounts or compromising existing accounts (Pascual et al. 2018).

Schemes

Data breaching – a form of cyber theft wherein sensitive data is stolen via computer hacking. There have been several high-level breaches since 2005. One of the more well-known and most recent instances was the 2017 Equifax breach where 143 million customer accounts and credit card data were compromised. In 2014, Yahoo had upwards of three billion accounts compromised. In 2013, target stores had 100 million accounts compromised costing them approximately $162 million, and Heartland Payment Systems had 134 million accounts compromised in 2008 costing the company $145 million to cover fraudulent payments. In January 2016, Austrian-based aerospace company FACC suffered an approximate €42 million ($47 million) theft via a hacking incident (Reuters 2016).

Data breaches were not solely confined to private entities however. In 2015, the Office of Personnel Management (OPM) revealed the PII of 21.5 million current and former federal employees with security clearances had been compromised. Also in 2015, the US Voter Database was incorrectly configured resulting in the release of the PII for over 191 million voters in all 50 states and the District of Columbia (Finkle and Volz 2015). In 2016, the Federal Bureau of Investigations was hacked, resulting in the release of the PII of over 20,000 employees.

Card-not-present fraud – this scheme is one of the elements resulting from skimming in which criminals will use the stolen credit card information to make online, rather than in person purchases. This type of fraud is expected to rise as more industries convert their credit card readers to accept the EMV chip technology used by merchants (ACFE 2018).

Account take-over fraud – criminals will use stolen information to access victim's financial account in an effort to withdraw or transfer funds. According to the JAVELIN Report (2018), this scheme increased 120% from 2016 to 2017 and resulted in $5.1 billion in fraud losses.

Jackpotting – this scheme is relatively new in the USA but has been previously committed in Europe and Mexico (Langone 2018). Jackpotting occurs when an individual/s poses as an ATM technician and uses an ATM key (which are readily available online) to gain access to the

inside of the ATM. A programmed laptop and cellphone are installed inside the ATM so the machine can be taken over remotely and forced to discharge cash at a rate of up to 40 bills every 23 s. According to the US Secret Service, the ATM will spit out money like a slot machine in a casino after someone hits the jackpot (Langone 2018). This scheme relies on multiple people as one person will act as the ATM technician, while others act as ATM customers to withdraw the illicit funds.

Forged or altered checks – an individual/s will steal or manufacture checks (by any of the methods previously outlined) to assume control of the funds in a legitimate bank account or to withdraw funds from counterfeit checking accounts. Criminals can alter legitimate checks and change the name of the intended payee, and in the case of stolen checks, thieves may forge the account holders' signature and write checks to an accomplice with a counterfeit identification, who will cash the stolen check.

Phishing – a social engineering crime in which an individual(s) is contacted by email, telephone, or some other method by someone who poses as a legitimate business or organization and attempts to coerce that individual to reveal sensitive PII or passwords, bank, and/or credit/debit card data. Phishers oftentimes create webpages similar in appearance to those of legitimate banks or other financial institutions and ask the respondent for PII to "verify" account information. Once the PII is entered, the Phishers can use the respondent's data to commit any number of fraudulent offenses.

Insider threat – this type of scheme involves an employee working at a merchant or financial institution who collects relevant data of customers and then either sells the information or uses that information to carry out fraudulent criminal activity.

Malware attack – a victim has an unprotected or not fully protected computer and is hit with a malware. This malware provides the criminal the ability to compromise that person's email account and monitor all email activity. The victim types passwords for a financial institution account, which gives the criminal an opportunity to access the account and transfer funds or open other fraudulent accounts in the victim's name.

What one man can invent another can discover.

–The Adventure of the Dancing Man

How

How Are State, Local, Federal, and Private Investigators Approaching Cases?

The Investigative Process

According to Bennett and Hess (2004), an investigation is a simple fact finding and reporting process that follows a patient, step-by-step process (4). Osterburg (1981) noted the process to be akin to the scientific method of solving problems, and it follows the five primary steps of the scientific method: stating the problem, forming the hypothesis, collecting the data by observing and experimenting, interpreting these data, and drawing conclusions. In the first step of the process, identifying the problem, the investigator must determine if a crime has been committed or if there is another explanation that would account for the current situation? In the second step, the hypothesis stage, questions can be raised about suspicious activities; "there appears to be a pattern of bank fraud committed with counterfeit credit cards." Step 3, the data collection phase, can be achieved through a combination of processes such as observation (stakeouts, reviewing video, etc.) and review of records or data files and/or through witness and victim interviews. Once the data has been collected, the next step is to analyze all the information. This step consists of sending evidence to the lab for analysis, conducting a more detailed review of the interviews, and possibly conducting more in-depth interviews. The final stage of the process is when the investigator has drawn a conclusion. This occurs when the investigator has determined who has committed the crime, with certainty.

While the investigative processes are similar between the two groups, the term "with certainty" is an important term to consider when

differentiating between public law enforcement investigators and private sector investigators. It can also be described as "burden of proof" or "fact beyond a reasonable doubt." Whichever term one wants to use, the way evidence is used is much more stringent for public sector law enforcement agencies, than it is for private sector investigators. Sennewald and Tsukayama (2015) explored this concept and others, as they related to the investigative practices employed by law enforcement and private sector investigators. They noted they are primarily the same with a few notable exceptions: the first being the objectives of both groups. Private sector investigators serve the interests of the organization of which they are employed, while law enforcement officers are beholden to the public at large. As such, the primary goal of law enforcement is not only to stop the continuation of the criminal activity and recouping the losses, but to also apprehend and punish the criminal's responsible for the criminal activity. A private sector investigator, however, may not have those same interests in mind, as the primary goal is to stop the activity and recoup the losses. They may not have any interest in public punishment of the criminal, as it might reflect poorly upon the organization because the investigation may expose lax financial or data controls employed by the organization. The second notable difference lies with the legal authority of each group. State, local, and federal law enforcements have their authority to conduct investigations and make arrests embedded in constitutional and state laws. Private sector investigators, on the other hand, are not constitutionally bound by Fourth Amendment rules, nor are they bound by Miranda rules.

Some private sector investigators will work cases independent of law enforcement, while the creation of task forces, like the US Secret Service Electronic Crimes Task Forces (ECTF) and Financial Crimes Task Forces (FCTF), has provided a working network of law enforcement and private sector investigators to work together in an information sharing capacity to address the growing threats of fraud to the financial industries. When working collectively in task force environments or when a law enforcement and a private sector investigator work together to investigate a singular crime, the relationship is geared toward the law enforcement goals previously outlined. The relationship also allows the groups to enhance their investigative performances by sharing their complimentary skills, experiences, knowledge, and resources.

Conclusion

While the success of bank fraud schemes has increased over the years with the growth of technology and the Internet, law enforcement and private sector investigators must remain vigilant in their efforts to collaborate in task forces and with information sharing. Achieving any level of success against the criminal element will require greater technological strides and outreach efforts to the public about the technological and non-technological vulnerabilities open to exploitation.

Investigations: Burglary

Heather A. Panter
Centre for Advanced Policing Studies, Liverpool John Moores University, Liverpool, UK

Keywords
Residential burglary · Commercial burglary · Burglar modus operandi · Stolen goods conversion

Definition

The FBI's Uniform Crime Reporting (UCR) Program defines burglary as "the unlawful entry of a structure to commit a felony or theft" (FBI 2017). A structure according to UCR includes "an apartment, barn, house trailer, or houseboat when used as a permanent dwelling, office, railroad car (not automobile), stable, or vessel (i.e. ship)" (FBI 2017). Burglary is subdivided into forcible entry, unlawful entry, and attempted forcible entry (FBI 2017). Further, burglary is separated into two distinct categories: (1) residential and (2) commercial. Notably, individual states may have different definitions, classifications, and criminal penalties. Burglary investigations entail appropriate first responder actions, the establishment of a burglar (s) modus operandi (MO), knowledge of property fencing operations, and subsequent examinations of forensic evidence for successful investigative apprehension.

Introduction

In 2017, the UCR estimates that 1,401,840 burglaries have occurred with 841,283 occurring within a residential dwelling (255,524 during night and 424,886 during day hours) (FBI 2017). Nationally, residential burglaries accounted for 60% of all burglary offenses (FBI 2017). Notably, the probability of residential victimization is higher during summer months and during daytime hours (FBI 2017). Comparatively, commercial burglaries are more likely to be committed during night hours when businesses are closed (FBI 2017). Overall, burglaries accounted for 18.2% of the estimated number of property crimes in the USA with an estimated $3.4 billion in property losses ($2416 average loss per burglary) in 2017 (FBI 2017). Further, studies have indicated that three million individuals are victimized annually in the USA (Langton and Truman 2015).

Besides the financial losses that burglaries cost nationally, they occur in more frequency comparatively than other felonies (FBI 2017). Notably, arrest rates and victimization data are only a fraction of an indicator of burglary incidents as most are not reported, do not result in arrest, and are not included in national statistics (DeLisi et al. 2018). For example, it is estimated that only half of burglaries are actually recorded within FBI Uniform Crime Statistics with 70% of all US residences being burglarized once within a 20-year period (Osterburg and Ward 2000).

The national clearance rate for burglary is 13.5%, which includes an arrest or a clearance by exceptional means (FBI 2017). Comparatively, murder and nonnegligent manslaughter has a 61.6% clearance rate with robbery having a 29.7% clearance rate (FBI 2017). Often burglaries are difficult to investigate because solvability is dependent upon the actions of the initial responding officer(s), the efforts of crime scene technicians in processing the scene, and the subsequent investigative efforts of detective(s).

Notably, a percentage of residential burglary clearances result from indirect methods when a burglar is arrested for another offense and admits to unsolved burglaries (Mawby 2013), with most first responder activities having a direct influence upon criminal apprehension (Coupe and Griffiths 1997). Coupe and Griffiths (1997) found that first responders detaining an offender in the act or near the crime scene (43% of clearances in 256 cases) alongside effective witness/victim statements (34% of clearances) were attributed to arrest. Farrington and Lambert (2000) found that burglars were most likely to be detected being caught in the act (14%); from information from an informant (12%); apprehended near the crime scene (12%); traced through stolen property or property left at the crime scene (10%); acting suspicious in the area (8%); through a witness description (7%); and through indirect detection (7%). Comparatively, forensic evidence as the principle method of direct detection (6% of clearances in 256 cases) and subsequent CID investigations (10% of clearances) should not be discredited when investigating burglaries (Coupe and Griffiths 1997).

Therefore, all burglary investigations entail an understanding of a burglar's modus operandi (MO) or specific pattern of criminal activity, particularly vital in cases where an arrest in not made by first responding officers. Deductions toward formulating a burglar's MO can be established by drawing typological inferences about how and why a location was selected, the burglar's method of entry, the items taken/not taken, the apparent pre-commission planning involved, and how the burglar searched the property for items. Once an MO has been established, investigators can link serial burglaries together, link a suspect to previous criminal cases, and determine the individual characteristics of a burglary.

Commercial Burglars Versus Residential Burglars

Research examining burglars has shown that commercial burglaries are often preferred over residential burglaries partly because offenders can more easily justify their crimes (Mawby 2013). Mawby (2013) contends that this justification is based upon offenders' perceptions of reduced victimology (i.e., no individual victim involved) and sentencing by courts and increased profitability for commercial over residential burglary. Another

difference between commercial burglar(s) and residential burglar(s) is that target hardening (e.g., presence of security staff, dogs, etc.) may deter burglar(s) (see Kruissink 1996; Wiersma 1996). Yet, what is unique to commercial burglaries is there is often more extensive preplanning with multiple suspects taking large quantities for "orders" (Mawby 2013). An investigative focus on fencing operations could be more vital in a commercial burglary investigation than residential burglary investigations because tracking numerous objects of one type (e.g., multiple TVs) as opposed to singular items is a key feature. Comparatively, a majority of commercial burglars have previous residential burglary convictions and/or disclosed a history of residential burglaries (Mawby 2013). Hence, there is often an investigative overlap between commercial burglaries and residential burglaries.

Following an investigative blueprint, the investigations of residential and commercial burglaries are relatively similar. Investigators should examine a burglar's typology and location selection, examine their method of entry and targeted items, determine the burglar's amount of pre-commission planning, establish how the property was searched, and any post-commission acts to identify potential items of forensic and investigative value.

Burglar Typology and Location Selection

An investigation of both residential and commercial burglaries relies on determining burglar typology and selection of the target location. By determining the typology and the motivations for why a location was targeted, and offender MO can be established which aids in determining who committed the crime. Determining an MO can allow investigators to link similar cases together, link offenses to specific offenders, understand how a crime has been committed, aid in the retrieval of forensic and investigative evidence, and predict future offending patterns.

Notably, research has indicated that across commercial and residential burglary offenses, there exists variability among burglars in terms of their criminality and their criminal career (Bouhana et al. 2016; Hargreaves and Francis 2014), burglary committed with other associated crimes (Fox and Farrington 2012; Steffensmeier et al. 2015), variation in burglar motivations (Wright et al. 1995), and geographic and temporal issues in relationship to burglary (Johnson 2008). While studies indicate that skill levels vary across burglars, often the typical burglary is intersectional with other crimes focused on property crimes to support drug dependencies (Wright and Decker 1994).

Further research (Cromwell et al. 1991; Wright and Decker 1994) indicates that the selection of a burglary target is often preplanned. Burglars often have some knowledge of the items inside a residence or business along with knowledge regarding the routine of the occupants/owners. Nee and Meenaghan (2006) found 45 out of 50 UK burglars had a predictable search pattern with familiarity with the residential layout and the types of property contained within. Therefore, investigators should put CCTV footage during the course of their investigation to see if the offender can be viewed casing the location pre-commission.

Residential Burglars

Wright and Decker's (1994) study of residential burglars in Saint Louis (USA) found that they target a location based on their observations (62%) prior to commission of the crime. Further, burglars disclosed that they watched a location for some time within an area of local familiarity before committing the crime (Wright and Decker 1994). In other words, burglars target locations that are within close proximity to their normal living activities. This can include targets near their own personal residence, targets near friends/families, targets near routes to work/school, etc. Research has indicated that burglars are more likely to target locations close to their residences (Chamberlain and Boggess 2016; Rossmo 2000), often residing within a 1–2 mile radius of the actual burglary location (Bernasco 2006; Snook 2004). Therefore, investigators should interview individuals near the area of the offense to see if a suspect was casing the area pre-commission.

Uniquely, residential burglars obtain information about the target from knowing the occupant (Wright and Decker 1994). Wright and Decker (1994) found that 21% of their studied burglars target neighbors, their drug dealers, or they had jobs that brought them into targeted locations (e.g., cleaners, delivery drivers, movers, utility workers, etc.). Rarely do burglars rely upon intelligence from others (6% according to Wright and Decker 1994). Hence, it is vital that burglary investigators question neighbors about people seen in the area recently, including workers with access to the area. In business burglaries, suspicious employees or recently fired employees should be questioned (Brandl 2018). Notably, burglars will often avoid occupied locations during the commission of the crime as it reduces the probability of eyewitnesses and potential confrontation (see Coupe and Blake 2006; Goodwill and Alison 2006; Rengert and Wasilchick 2000).

Affluence cues also influence location selection. Burglars' perceptions of affluence may be based on observations of the size of the property, condition of the property, and the types of vehicles associated with the property (see Bernasco and Luykx 2003; Nee and Meenaghan 2006; Wright and Decker 1994). Burglars' observations through knowledge of expensive purchases within the residence can also affect affluence perceptions. For example, if residents dispose of a flat screen TV boxes outside of their home for garbage collection, one could easily conclude that the residents have new TVs inside their premises.

Commercial Burglars

Neighborhood familiarity affects location attractiveness for both residential and commercial burglars for several reasons. Ethnographic research has indicated that burglars favor locations in their own neighborhoods because they can blend in more easily without raising suspicion (see Rengert and Wasilchick 2000). Further, neighborhood familiarity affords burglars fewer demands upon pre-commission planning than do other unfamiliar areas (Chamberlain and Boggess 2016). Neighborhood familiarity also provides burglars knowledge of the area, knowledge of police patrol activities, and information on the people or property involved (Chamberlain and Boggess 2016; Wright and Decker 1994).

Butler (2005) found that commercial burglars appear to target larger stand-alone businesses located on the outskirts of a major town. Butler (2005) argues that commercial burglars target these businesses because the probability of apprehension is lower with police being located further away. Further, Cromwell et al. (1991) stated that commercial burglary responses might be up to 20 min to locations outside city centers that affords burglars more time to avoid apprehension. Yet, conflicting research found that inner-city neighborhoods are also more likely to be targeted because of the increased probability of the number of offenders living close to the location (Clarke 2003). In respect to the presence of security guards, they are a sight deterrence regarding commercial burglary target selection with CCTV being a potential deterrent dependent on if it is physically being monitored by security (Butler 2005).

Burglar's Method of Entry and Targeted Items

Residential Burglaries

How a burglar gains entry to a residence or business contributes to a further understanding of a suspect's modus operandi. Weisel (2004) found that two-thirds of burglaries involved forced entry through windows, doors, and back doors. Forced entry into these common entry points involved the usage of screwdrivers, crowbars, rocks, hammers, or the burglar may kick a window or door through. Weisel (2004) found that one-third of residential burglary cases involved entry through unlocked doors/windows, or open doors/windows. Often doors and windows will be checked before a burglar makes forced entry. Burglar(s) may check for uncollected mail, ring doorbells, knock on doors, or call the resident to verify occupancy pre-commission (Hakim et al. 2001; Nee and Meenaghan 2006; Palmer et al. 2002). Hence, it may be productive to dust other points of entry for fingerprints contained within the same residence/business.

Based on my professional experience as a burglary detective for several years in the USA, I observed that novice burglars were more likely to use pillowcases or bags/luggage taken from the crime scene to transport stolen items. This is why it is crucial for first responders to ask victims to describe any bags/luggage that could be used for concealment of stolen items in a police lookout. For larger items, like flat-screen TVs, often novice offenders would place garbage bags over the item during transport for concealment purposes. Hence, first responders to residential burglaries should stop suspicious individuals (those on foot and on bicycle) in the area carrying bags/luggage reported missing from the burglary, pillowcases reported missing from the burglary, and large items sticking out of garbage bags. In some cases, burglars may also steal wheelie bins during garbage collection day and store the stolen items within them for easy transport. In these cases, stopping a suspicious individual pushing a wheelie bin down the street outside garbage collection times is easily justifiable. Further, wheelie bins often have the address scribed on them, which could be connected to a burglary location during the investigation.

Besides possible containers used to transport stolen items, it is also beneficial to determine if any bicycle was taken from the victim's residence for two reasons: (1) it often indicates that the burglar has ridden the said bicycle from the incident location and arrived on foot; and (2) it aids in providing a more detailed suspect lookout for surrounding first responders. Based on my experience, burglars who steal a bicycle from the crime scene often did not arrive to the location via a vehicle. Notably, it would be rare for a bicycle to be taken by a burglar who used a vehicle post-commission of the crime.

The most common items taken during a residential burglary are things that can be easily converted to cash and easily carried away from the crime scene. For example, the most common taken items from 1,401,840 burglaries annually are currency ($1,429,781,653), jewelry ($1,362,002,838), clothing ($362,025,765), electronics ($938,765,508), and firearms ($155,186,427) (FBI 2016). Felson and Boba (2010) contended that items that are concealable, removable, valuable, enjoyable, and disposable are more likely to be taken during the commission of a burglary. Often this includes currency, jewelry, laptops, gaming consoles, iPads/tablets, etc. instead of furniture, refrigerators, washing machines, or dryers. As such, the items taken are based on the burglars' perception of value and/or their fondness of the items combined with offender mobility. Therefore, a burglar may steal beer from a fridge while leaving behind an expensive bottle of wine. Alternatively, a burglar may steal a gaming console and leave behind an expensive painting located nearby on a wall. Notably, stolen items can lead to investigative deductions, which may lead to a suspect.

Commercial Burglary

Commercial burglars' main motivation, like residential burglars, are economic in nature. Yet, commercial burglars are more likely to work in groups disabling alarms and targeting safes located inside businesses (Clarke 2003). Entry is often made in similar patterns as residential burglaries through doors and windows. Yet, 2% of commercial break-ins involved the usage of a vehicle to ram through doors or windows (see Mirlees-Black and Ross 1995).

Successful commercial burglaries, like residential burglaries, are more likely to be targeted with repeating substantial victimization due to the offender(s) gained knowledge during previous commissions. Variations in burglary risk differ among businesses due to location, premises, items sold, and security. For example, stores which are open 24 h are less likely to be targeted due to employees being present as potential witnesses, whereas a store with closing hours at night with lesser-known security measures are more likely to be targeted.

In respect to product targeting inside businesses, commercial burglars are more likely to target banks and cash registers, tobacco products, health and beauty products, electronic goods, and designer clothing (Clarke 2003). Further, research indicates that commercial burglars may target ATMs located inside businesses (see Clarke 2003).

Burglar Variances in Pre-commission Planning

Residential Burglars

Two demographic characteristics, age and gender, of burglars are associated with different pre-commission planning in both residential and commercial burglaries. Experienced burglars typically are middle-aged adults, steal highly valuable items, and commit "high-risk" burglaries (Brandl 2018). Weisel (2004) contended that experienced commercial and residential burglars are also more likely to commit offenses farther away from their homes than novice ones. Notably, experienced burglars use more advanced preplanning than do novice burglars. Experienced burglars will often bring entry tools and a bag (to carry stolen items) with them pre-commission. Experienced burglars often avoid taking aged electronic goods, instead opting for smaller and more portable electronic items, jewelry, drugs, and cash (Nee and Meenaghan 2006).

Novice burglars, on the other hand, are typically poor preplanners, stealing in a spontaneous way motivated by opportunity, fun, or excitement (Cromwell et al. 1991; Walsh 1980). Novice burglaries often involve minimal gains and often target nearby residences that do not have dogs, alarms, or locks (Brandl 2018). Further, both experienced and novice burglars prefer locations that allow them to remain unseen, such as areas with fences or natural covers that hide entry locations and building with few neighbors (Bernasco 2006; Coupe and Blake 2006; Sanders et al. 2017). As such, these types of locations reduce the probability of confrontation from a third party and/or any witnesses to the incident.

Researchers (Sanders et al. 2017) comparing residential burglaries found that male burglars are more likely than female burglars to engage in some type of intelligence planning pre-commission as the latter appear to be impulsive overall. Yet, female burglars have reported that they are more likely to be deterred by alarms, outdoor cameras, outdoor lighting, and indicators on neighborhood watches than are male burglars (Sanders et al. 2017). It is speculated that female burglars are more likely to be impulsive in the commission of burglaries because they are more involved, or motivated by, substance abuse problems than are male burglars (Sanders et al. 2017). Often women are more likely than men to take prescription narcotics from a residence. Female burglars often commit the burglary with significant others, whereas male burglars commit burglaries with friends (see Sanders et al. 2017).

Commercial Burglars

The degree of pre-commission planning for a commercial burglary may vary based on the type of location burglarized. For example, Butler (2005) found that most commercial burglars disclosed that they spent 20 min to a few hours to plan a business burglary based on security factors. Blevins et al. (2012) found in a sample of 422 convicted burglars that close proximity to other people, lack of escape routes, and indicators of increased security (alarm signs, dogs, outdoor cameras, etc.) are considered in pre-commission planning of a target. Further, 60% of burglars stated that the presence of an alarm would deter them, especially burglars who spent more time with pre-commission planning (Blevins et al. 2012). Notably, Butler (2005) contends that the amount of planning is dependent upon the professionalism of the offender. More experienced burglars are more likely to take more time with pre-commission planning to consider all the risks and factors that may influence criminal detection (Butler 2005).

Burglar's Property Search for Items

Nee and Meenaghan (2006) found that out of 50 experienced residential burglars, 45 had a predictable search pattern once inside a property that lasted under 20 min. Further, Nee and Meenaghan (2006) found that habitual residential burglars engage in a search based on what has worked in previous burglaries alongside what yields the highest gains at the lowest risk. Researchers (Nee and Meenaghan 2006; Wright and Decker 1994) found that burglars often begin their

searches in the master bedroom of a residence with the most common place searched being the kitchen followed by bathrooms (Wright and Decker 1994). Therefore, a burglar's actions during searching for property may indicate preplanning knowledge of contents of the premises (Brandl 2018). For example, a frenzied ransacking style within the crime scene is an act either of vandalism (most likely juvenile offenders) or because of poor strategic preplanning to search the premise for property (Brandl 2018). If burglar (s) have preplanning knowledge of the location of targeted items, evidence of ransacking will be minimal and the time span for the commission of the crime will be smaller. This type of preplanning can be evident within crime scenes if cabinets and drawers are left untouched and areas which contain valuables are specifically targeted. This can indicate to burglary investigators that the burglar is either a friend/family member of the victim, or a cleaner who knows where items are located in the residence. Further, the degree of ransacking is negatively associated with the relationship between the burglar and the victim (e.g., high ransacking, strangers).

Commercial burglars are more likely to visit a business prior to a burglary commission. By visiting an open business, commercial burglars can familiarize themselves with the goods and items within the targeted business and the observable security perimeters present. As such, viewing CCTV footage from several days prior to the burglary may yield an investigative lead in identifying a suspect. Further, some research indicates that commercial burglars spend less than 30 minutes inside the targeted building during the burglary (Butler 2005).

Burglary Post-commission Acts

After the burglary, burglars commit further actions that hold investigative value. Studies indicate that the main motivating factor for the commission of a burglary is to acquire cash (Palmer et al. 2002; Wright and Decker 1994). Yet, studies vary on why burglars need said cash (see Bennett and Wright 1984; Palmer et al. 2002; Wright and Decker 1994). While some burglars commit burglary for subsistence and daily expenses along with superficial factors (see Shover and Honaker 1992), often the motivation for the commission of a burglary is based on drug addiction (Hochstetler and Copes 2006; Wright and Decker 1994), particularly heroin addiction (Weisel 2004). To sell stolen items, often burglars will significantly "markdown" (Felson and Boba 2010) items to get rid of them quickly. Ferrante and Clare (2006) found that stolen goods are typically converted within hours and mostly within a day of the burglary. Felson and Boba (2010) contended that "markdowns" occur in the process of converting items to cash due to the stolen item being damaged during the burglary, as a result of being used, as a result of being stolen itself, and as a result of the burglars desire to move the item quickly.

Further, the process of turning property into cash involves varying levels of risk and effort for burglars with investigative possibilities for investigators to follow-up on (see Chart 1 below). Wright and Decker (1994) contended that stolen property is often converted within hours of the commission of the crime. As indicated in the Chart 1 below from Brandl (2018), stolen items

Method	Effort Level	Reward Level	Risk Level of Arrest
Sell stolen items to friend	Low	Low	Low
Trade for drugs	Low	Low	Low
Sell to a fencing operation	Moderate	Moderate	Moderate
Sell to a pawnshop	Moderate	Moderate	High
Sell to strangers	High	High	High

Investigations: Burglary, Chart 1 Methods of converting stolen items from burglaries versus effort and risk (Brandl 2018)

are more easily executed with a low level of risk when items are traded for drugs. Therefore, burglary investigations often coincide with narcotic investigations as it is not uncommon to execute unrelated narcotic warrants and recover stolen items taken from previous burglaries in the area.

Physical Evidence Located and the Burglary Scene

Often a search of physical evidence at a crime scene will require assistance from the victim to determine which items have been left behind, touched, or moved during the commission of the burglary. Overlooked physical evidence within burglary crime scenes are tool marks, discarded cigarettes, matchbooks, and fingerprints/footprints outside points of entry. Determining the path of burglar(s) through a residence or business is vital in the recovery of forensic evidence during the establishment of an MO. Forensic efforts should be concentrated in locations where it can be determined that the suspect(s) touched during the commission of the offense. During this search for forensic evidence, a common approach path should be taken by investigators and forensic technicians alike to reduce the likelihood of crime scene contamination. Often, departments may not have available forensic personnel and the first responder and investigator may be tasked with processing the crime scene themselves. This processing involves taking relevant photos, dusting locations for fingerprints, recording items and serial number for documentation, and subsequent follow-up of any items of investigative value.

Notably latent print recoveries are more probable during burglary investigations because burglar(s) search and touch items while looking for items of value. Additional areas that should also be examined for latent prints include contents within refrigerators as the burglar(s) may have taken food; any discarded beer/soda cans; toilet seats if the restroom has been used; etc. Suspected prints should be dusted according to department protocol and a chain of custody which documents who processed the prints alongside the recovered location should be upheld at all times to avoid contamination.

Based on my investigative experience, prints can often be found on the bottoms of dresser drawers that have been removed for searching. I also observed that when it rains and is cold, socks drawers specifically are more likely to be searched as the burglar(s) steal dry socks. In this scenario, a burglar will leave behind their wet dirty socks nearby. This modus operandi can aid investigators in concluding the suspect arrived and left the scene via foot instead of a vehicle.

Besides the recovery location of latent prints inside a crime scene and the linkage to a burglar (s) modus operandi, the advancement of the Automated Fingerprint Identification System (AFIS) is valuable in burglary investigations. AFIS technologies allow for recovered latent prints to be compared to the prints electronically archived in criminal records. By using ridge endings and bifurcations contained within criminal record fingerprint files, digitalized representation of fingerprints can be stored and then compared to digitally inputted suspect fingerprints. Notably, a fingerprint examiner can only verify an official fingerprint match manually as the AFIS system only narrows down a potential suspect sample. As there are 90+ unique identification points on each finger, even partial prints may be run on AFIS (Osterburg and Ward 2000). Notably, at least 13+ identifiable points are needed for an identification in the USA; comparatively, France requires 17 points of reference and England requires 13 points of reference for identification (Osterburg and Ward 2000).

Besides forensic techniques that can connect burglar(s) to burglary scenes, clearance rates of burglaries often reside upon records and information about stolen property. Electronics, handguns, bicycles, and other items have unique identification numbers. Therefore, if a victim has recorded and documented unique serial numbers they can be compared to pawn system databases, National Crime Information Center (NCIC) databases, items founded in narcotics warrants, and items recovered in other crime scene locations. By

having comparative record numbers, the burglary can be effectively prosecuted. Often, a suspect will not face prosecution if there is nothing unique or identifiable about a stolen item. Currently, there exist no formal stats on the success rate of the recovery of stolen items with serial numbers, yet when examining FBI statistics, recovered items documented are more likely to have a higher probability of formally recorded serial numbers (e.g., vehicles, handguns, large office equipment, large electronics).

Further, a specific lookout can be placed for any stolen material with a known unique identification number on NCIC, which is used nationally to trace items by law enforcement. If items with a known unique identification number are taken, the odds of successful investigative recovery are greatly increased. Hence, it is vital that both businesses and residents document the serial numbers of valuable items. Notably, if a suspect is stopped after the commission of a burglary and is in possession of similar items taken from a burglary without identification number verification, it could not be judiciary concluded that said items are the same as those burglarized.

Conclusion

During a burglary investigation, the establishment of a modus operandi can identify an offender and provide the basis for apprehension. Further, the establishment of a modus operandi in a burglary investigation can link serial burglaries together and link a suspect to previous criminal cases. Possessing a better understanding of empirical studies of burglars, burglar crime analysis, burglar crime commission, and post-commission actions can aid investigators in narrowing their search for physical evidence within a crime scene. For example, having a better knowledge of a burglar's MO may aid in determining potential latent print locations within a residence/business. Further, the successful recovery of "readable," identifiable prints may assist in identifying a burglar (if their prints are on AFIS). Besides offender identification and typology in burglary investigations, the conversion of stolen property with unique identification numbers can additionally aid in apprehension of suspect(s) and the recovery of stolen items. Therefore, there are several possibilities that investigators can explore in conducting a burglary investigation from their interaction with first responders; to an adequate immediate search for suspect(s); to effective questioning of witnesses; to the successful processing of a scene; and to the subsequent examination of traceable items with unique identification numbers on NCIC.

Retail shoplifting · Retail theft · Shop theft · Shrinkage · Concealed goods

Definition

Consumer retail shoplifting, also referred to as retail theft and shop theft, can be defined as the stealing of consumer goods from a retail outlet. This act of larceny/theft, i.e., intentionally and unlawfully taking possession of the property of another, is usually classified as shoplifting when it is done by the shopper or people pretending to be shopping during the opening hours of the store. If the shopper leaves the outlet and forgets to pay for the goods, then this would not be considered as shoplifting as the element of intention is missing.

Introduction

The scholarly work on shoplifting is largely located within the disciplines of criminology and consumer behavior with many of the studies done on the characteristics of the shoplifter, causes of the behavior, shoplifting prevention strategies, and consequences (or lack thereof) of engaging in the act of shoplifting. This phenomenon continues to have a significant and negative impact on the retail business industry despite the enactment of civil shoplifting statutes aimed at mitigating this problem in countries such as the United States. These statutes permit the retailer to recover damages and enforce penalties against the culpable shoplifter.

As the economy gets tight, shoplifting is expected to increase as people will find a way to satisfy their needs and desires. As such, the retail business form will naturally lose money due to shrinkage. The term shrinkage refers to the unexplained loss in inventory due to theft, shoplifting, errors, and fraud (National Retail Federation 2018) with shoplifting being the largest source of these lost revenues (Du and Maki 2019).

The large majority of shoppers have stolen from retail stores at some time during their lives. And while this is *eye-opening*, it is unfathomable to conclude that most of these people are criminals (Cox et al. 1990). That said, only 1 in 11 shoppers is engaged in shoplifting on a regular basis (Blanco et al. 2008), and 1 in 150 shoplifters is apprehended by the police (Farrington 1999). Police data on shoplifting is problematic as only a small portion of the crime is reported (ONS 2014), and the percentage of shoplifters who get caught is very small.

The act of shoplifting is usually committed by shoppers or people pretending to be shopping and involves the concealing of the items and leaving the store without paying for these items. Other forms of shoplifting would include fake refund, switching of price tag and paying the lower price, and eating of food in grocery stores without making payment. Fake refund does not involve the direct stealing of an item but rather the illegal taking of a cash refund for goods from a store where the goods were not purchased. There is also the notion of digital shoplifting where people illegally photograph materials from books for reading later.

Retail theft can be committed at any time but is usually at its lowest in the early mornings and highest in the early evenings (Bamfield 2012). It has been said that shoplifting is more popularly committed during busy periods like public holidays and stores are more vulnerable at times such as just after opening, just before closing, and during shift changes. Moreover, retail theft is most likely to happen when sales staff are

occupied or distracted. These offenders will try to distract store personnel by asking questions that will lead the staff away from their stations thus giving the perpetrator enough time to make the move. For example, questions about out of stock items could lead the store personnel to the warehouse or to the back of the store and leaving the shoplifter with wiggle room to commit the act. Product categories that are popularly shoplifted include electronics, cosmetics, and clothing.

The layout of the modern retail concept is very accommodating to the shoplifter as holding areas for stealing goods are facilitated through shelves, spaces, and secluded areas within these stores. Goods that are shoplifted are then concealed in pockets, coats, oversized clothing, handbags, and backpacks – a favorite carrier among petty thieves for hiding stolen items. There is also the case where shoplifters will conceal goods such as clothing or a wristwatch by wearing the item in plain sight when leaving the store. Some shoplifters will even purchase one item to conceal another in the packaging.

The fitting room area is also a popular space to conceal goods. In this area, the shoplifter will pack bags with stolen items, switch tags with cheaper ones, and bring a lot of clothing items in dressing rooms so that sales representatives cannot be certain of what is taken and what is left behind. The shoplifter will try to make a speedy exit when in possession of the stolen items. However, this is not usually done by running away from the scene but by walking away briskly so as not to attract attention. Store employees should therefore be proactive and look out for these suspected personalities as they can often be found loitering in the stores, showing signs of excessive sweating, fidgeting, and displaying other nervous-type behaviors.

The motivation for shoplifting is not fully understood as the large majority of shoplifters indicate that there was no plan or intention to steal before entering the store which therefore suggests that shoplifting may be due to stimulus-response, i.e., an impulsive behavior in large measures and not to criminal intent. Most shoplifters are therefore amateurs and not professional thieves. Amateurs usually steal on impulse for personal use and utilized methods that are crude and simple. These people do not consider themselves as criminals and are often distraught when described in such terms. When caught and subsequently arrested, these amateurs will often express disbelief when treated as criminals. The professionals, on the other hand, are usually skillful and habitual thieves with criminal intent and may steal on their own or may utilize a ring of criminals to steal and sell for making profits. These professional thieves utilized methods that are carefully orchestrated and are usually knowledgeable about the shop layout, knowing what they want and where to get it. Taylor (2011) described three scenarios involving techniques that are utilized by professional shoplifters (Table 1).

The cost of shoplifting is borne by the honest consumer as the practice is to offset the retail losses by increasing the price to consumers. However, if the competition makes it

Investigations: Consumer Retail Shoplifting, Table 1 Techniques utilized by professional shoplifters

1. Booster Box
• Shoplifter enters store with large box on trolley.
• Box has identifiable image, such as a large television, with tag from another store displayed.
• Box is empty on entering but looks full, with visible packaging tapes around it.
• Box is then filled with shoplifted goods from underneath and tape affixed at the bottom to ensure goods do not fall out.
• Shoplifter then leaves the store with box on trolley and is not challenged by store personnel as product is clearly identified as being bought elsewhere.
2. Double Docketing
• Shoplifter loads two trolleys with same or similar items then and goes to cashier with one trolley with the other left behind.
• Shoplifter then pays for goods, collects receipt, exits store, and unpacks goods.
• Shoplifter then reenters store, picks up the other trolley with an additional item, returns to same cashier, pays for item, produces previous receipt, and explains to cashier that item was forgotten and returning in line was merely to pay for the additional item.
• Shoplifter then exits store with other trolley.
3. Distraction
• At least two people who are working together enter the store.
• One party distracts store attendant, and the other party takes goods and exits store.

infeasible to increase prices, then the retailer will have to absorb the losses. And even though retailers are under pressure from consumers to reduce prices, many retailers will not allocate the necessary resources to combat the shoplifting problem as there are so many competing needs for the limited resources. Moreover, most retailers do not have the will to combat shoplifting as detection and prosecution take time and energy and the mistaken apprehension of shoppers may result in costly lawsuits. Further, stores could acquire a bad reputation of crime if shoplifting were to be reported regularly (Clarke and Petrossian 2003). Shrink is estimated to cost retailers 1.33% of sales in the United States (National Retail Federation 2018) and US$400 per shopper on an annual basis (Brickhouse Security 2015).

Classifications of Shoplifters

Shoplifting is widespread and is one of the most prevalent forms of criminal activity. These offenders can be found among all ages, sexes, and economic and ethnic groups. There are reports that suggest that shoplifting may even be prevalent among high-income and highly educated individuals (Blanco et al. 2008). As such, shoplifters cannot be easily identified based on demographic variables. Hence, we must seek to uncover other classifications if the business is to effectively identify these offenders.

There are at least two broad classifications of shoplifters – economic and psychosocial. Economic motivators are displayed by individuals who take part in these activities for profits, while psychosocial motivators are more complex and are driven by dispositions such as peer pressure, impulsiveness, excitement, low self-esteem, stress, and compulsion. Thus, shoplifting is often triggered by need for financial gains along with a variety of psychosocial issues that are experienced by people who are otherwise law-abiding. The perpetrators of shoplifting could also be classified into groups such as professionals, kleptomaniacs, drug abusers, poverty stricken, and excitement seekers. See Table 2.

Investigations: Consumer Retail Shoplifting, Table 2 Classification of shoplifters

• **Professionals** – habitual stealing for profiting in a natural course of living
• **Kleptomaniacs** – inability to contain the urge for stealing and typically done for reasons other than personal use or financial gain
• **Drug abusers** – steal to maintain drug habits
• **Poverty stricken** – steal because of need of basic items
• **Excitement seekers** – steal because of the thrill from excitement caused by the adrenalin rush

Identifying the Shoplifter

It may be difficult to pinpoint who exactly will shoplift as this question is confounded by so many factors and reasons. Some of the reasons for committing this crime include necessity, desperation, desire of luxury items that offenders cannot afford, and psychological diseases such as kleptomania and other compulsive disorders. Thus, shoplifting is a complex behavioral issue that has no easily defined template for identifying the offender. Moreover, it is difficult to ascertain what the shoplifter looks like since there are no distinct physical traits as these perpetrators are likely to be male or female of any race or ethnicity and may be rich or poor (Pilon 2019). Notwithstanding this complex problem, in the identification of the shoplifter, there are many telltale behavioral cues that the retailer must utilize. The more typical signs and signals are summarized in Table 3.

Some of these behavioral types can be found among honest shoppers in the course of doing their shopping. However, these telltale signs and signals, while not exhaustive, provide a basic *snapshot* of the expected behaviors among shoplifters.

Preventing Shoplifting

High-value goods placed at the entrance of retail stores are known to attract patrons into these stores and at the same time provide easier access to shoplifters to grab and run away with the goods.

Investigations: Consumer Retail Shoplifting, Table 3 Signs and signals of the shoplifter

• Frequent users of washrooms
• Entering stores with large numbers of bags and bundles
• Wearing large and out of season clothing
• Leaving store in a hurry
• Moving in an unusual manner
• Loitering in the store
• Showing signs of excessive sweating, fidgeting, and other nervous-type behaviors
• Regularly picking up and putting down items

Investigations: Consumer Retail Shoplifting, Table 4 Shoplifting prevention strategies

• Increase the number and visibility of uniform security guards
• Utilize plainclothes store detectives
• Use security personnel to patrol aisles in store
• Redesign store layout to have a bird's-eye view of all areas
• Limit the number of changing rooms in clothing department and have sales person take inventory of the items entering and leaving the changing room
• Keep bags for shoppers on entering and returning them on leaving store
• Limit the number of exits from store
• Position cashiers in close proximity to store exit
• Install closed-circuit television (CCTV) monitoring and convex mirrors
• Install radio-frequency identification (RFID) anti-shoplifting technology
• Lock away small, expensive, and popular items in showcase
• Affix expensive items to shelves or clothing racks
• Utilize split-apart labels which will pull apart with attempts to remove
• Use large packaging for small item, making more difficult to hide
• Install facial recognition technology
• Post deterrence signs in strategic areas
• Utilize merchandising tags with sensors and sound alarms
• Participate in at-risk-youth programs with police and schools
• Check the purchase against the receipt
• Provide employee training on awareness, detection, and prevention strategies

This presents a problem for the retailer as the showcasing of goods in conspicuous spaces is a tried and proven practice for attracting customers to retail outlets. The challenge of the retailer therefore is to keep shoplifting at a minimum if not totally eradicated. However, the store is faced with the dilemma of deciding how much of the goods to display as it is generally agreed that the more goods that are openly displayed, the more is the likelihood of increasing sales and inciting shoplifters. To address this dilemma, the entity must embark on a loss prevention strategy.

In rolling out this strategy, it is important to measure the extent of the shoplifting problem. This is usually measured using the ratio of the shoplifting loss to sales. Small retailers may have more difficulty to establish the levels of shrink as they are not able to acquire elaborate inventory management systems. This initial size-up of the problem is done to establish a baseline for comparing shoplifting losses before and after the preventative intervention. The prevention strategy should then be monitored and evaluated to determine the effectiveness of the shoplifting intervention. Some of the practical intervention strategies utilized by retailers are summarized in Table 4.

Retailers are now using technologically advanced methods such as cyber and analytics to prevent shrink. Investigative experience, employee integrity screening, and loss prevention awareness programs are also utilized to curtail this problem.

Even though employees are often trained to exercise vigilance in the direct confrontation with shoplifters, this is a risky strategy as these employees could be harmed by violent perpetrators. Many retail outlets have therefore advised employees to limit direct confrontation with shoplifters to verbal exchanges and not to be physically engaged in apprehending these offenders. Some of these strategies such as checking of the shopper's bags and searching of the person may not be legal in some jurisdiction without probable cause.

Other soft but effective strategies that retailers can utilize to discourage shoplifters are to approach each customer with a sense of immediacy, always greeting customers, offering to help them to find what they are looking for, and never leaving the vulnerable points in the store unattended. Greeting customers on entering the store is not only for the purposes of courtesy and

customer service but to signal to the would-be shoplifters that they are on the radar of the retailer. This simple intervention may lead to rethinking and changing of the mind of the potential shoplifter. With the effective execution of this suite of strategies, the would-be offender will certainly realize that this is not the time and place to steal. The onus is therefore on the retailer to implement and monitor shoplifting prevention strategies to mitigate this crime.

Is Shoplifting a Lesser Crime?

The act of shoplifting is not to be confused with burglary or robbery since burglary refers to the unlawful entry into a building with the intention to steal while robbery is defined as the unlawful taking of property using force or the threat of force. In most jurisdictions, shoplifting is prosecuted under larceny which has two categories – grand larceny, a felony associated with a higher dollar value of goods stolen, and petty larceny, a misdemeanor associated with a lower dollar value stolen. These dollar values may vary from one jurisdiction to the other. In the strictest sense, shoplifting could be classified as felony or misdemeanor depending on the dollar value of goods stolen. Nonetheless, it is the view of the typical shoplifter that the financial benefit derived from the act far outweighs the risk and the associated penalty is seen by these shoplifters as a *slap on the wrist*, at worst. This notion was highlighted by Solomon and Ray (1984) in the eight common beliefs of the shoplifter. See Table 5.

Investigations: Consumer Retail Shoplifting, Table 5 Eight common belief of shoplifters

- I will not get caught if I am careful and smart
- I will not be turned in and prosecuted even if I get caught
- The punishment will not be severe even if I am prosecuted
- The merchants deserve what they get
- It is OK for me to do so as everyone does it at some time or another
- This is not a major crime
- The items that I shoplift are the items I want
- The merchant expects me to shoplift

Offenders seem to have less inhibitions in stealing from shops, a property crime, than from stealing from private individuals, an offense against the person, as they believe there are less chances of being caught with shoplifting, and if caught, there are much less consequences as they can get away with plausible excuses such as forgetting to pay (Clarke and Petrossian 2003). These common beliefs of the shoplifters demonstrate a maladaptive way of thinking and lack of moral concern among this group.

Some observers such as Elder (1989) and Klemke (1992) have suggested that this act of larceny is not perceived as a serious crime by society; and others, such as Brodsky et al. (1981) and Kraut (1976), have even referred to the act as a *folk crime*, thus alluding to the trivial way that the crime is often treated. There is also the view among some retailers that the criminal justice system does not treat the crime seriously as the cases are given low priorities and many convictions have resulted in cautions (Bamfield 1997). In general, crime against property, such as shoplifting, is not viewed as seriously as crime against the person, and police charges are often downgraded on these crimes.

For a conviction of shoplifting, the act (*actus reus*) of shop theft must take place, and the person so accused must possess the intention (*mens rea*) to commit such crime. In actuality, the penalties of shoplifting (if convicted) are usually less than other larceny crimes and are usually up to the judge's discretion in most jurisdictions. It is not uncommon therefore, particularly for first-time offenders, for the penalty of shoplifting to simply be *to return the stolen goods*, *pay for the goods*, or these perpetrators may just be given a *reprimand and warning*. Notably, shoplifters do not usually commit other crimes and are not perceived as criminals by many people.

Taking Action Against the Shoplifter

The management of the store should utilize a systematic approach for taking action against the shoplifter. First, when shoplifting is suspected by the security or employees of the store, the store

management should be contacted speedily for the necessary actions to be taken. Second, the suspected offender(s) should be allowed to exit the store before any detention is made as the accosting of a perceived customer within the store may send negative signals to other customers, who, as a result, may decide not to further shop at that store. Third, the suspect should be invited to a private space in the presence of the manager aimed at resolving the discrepancy, making effort not to accuse the suspect of theft during the detention. Notably, a false accusation could result in an expensive lawsuit. Fourth, the police should only be called on reasonable suspicion of shoplifting. That is, the police should not to be called on trivial matters as this could lead to the *cry wolf* syndrome with the effect that the retailer is not believed by the police when help is really needed.

Conclusion

The act of consumer retail shoplifting is perhaps the most prevalent form of criminal activity. This is because a large proportion of the population has stolen from a retail store at some time or the other. This activity has a negative multiplier effect on the economy and should be viewed as a significant menace to society. In effect, it contributes to the shrinkage losses of the retailer, increases the price to consumers, reduces taxation revenues to government, and increases the case burden on the court system.

Retailers must therefore be proactive in preventing shoplifters from concealing their goods in pockets, bags, and clothes since many of these goods may not have the alarm devices affixed, and so concealment provides an easy path to stealing. The active monitoring of cameras will also go a far way in resolving this concealment issue as shoplifters will never feel safe when they know that they are being watched. Further, several staff positions in retail outlets, such as cleaners and shelf packers, will be engaged in work before stores are open and after they are closed. This is usually done in preparation for opening the store. In order to add another layer of monitoring, the work rosters of these stores could be redesigned to allow enough staff to work during opening hours – the time that defines shoplifting. In that way, there will always be an attendant in place to *blow the whistle.* Greeting of shoppers on entering the store and helping them to find what they are looking for could also signal to potential shoplifters that they are being monitored.

In the final analysis, it is difficult to pinpoint the shoplifter based on appearance as these perpetrators can be found across all demographic and behavioral types. And while there are many telltale signs and signals that will help in the identification of the shoplifter, these indicators are often not reliable. Security personnel within these retail stores, while not ignoring telltale signs and signals, should continue to focus attention on large handbags, coats, and oversized clothing as concealment can hardly be successful without these carriers.

Definition

Criminal investigations involve systematic series of actions by an investigator, guided by the penal code for a jurisdiction in which the crime occurred, that uncover or make available facts that could be used to identify, locate, and prosecute a suspect (e.g., prove guilt).

Introduction

A complete criminal investigation includes searching, interviews, interrogations, evidence collection and preservation, and various methods of investigation (Woods 2013). The steps involved are governed by penal codes that involve an overlapping system of governments and the legislated laws pertaining to their areas of responsibility (Nemeth 2018). This layering begins with local government that includes the city, township, county, or municipality. In more urban areas, the municipal government may have layers of both a local and county government, but these entities legislate through ordinances that generally regulate behavior of very minor offenses and are often more concerned with building code and regulations than criminal offenses.

The next layer is legislating criminal behavior by the state of providence. In this realm is where

the bulk of criminal behavior is codified as there is a vast array of offenses from the state or provincial government (Nemeth 2018). These statutes become categorized by offenses based upon the seriousness of which the action is considered. Most jurisdictions divide these crimes into three basic categories – summary, misdemeanor, and felony (Nemeth 2018). Summary offenses (e.g., public drunkenness, harassment, vandalism) are the lowest level of criminality and generally require very little investigation to determine the offense and the individual who perpetrated it. Misdemeanor offenses (e.g., fraud, theft, minor assaults) are behaviors conceived as contrary to public good or as producing increased suffering by the victim. Felonies (e.g., murder, rape, burglary) are considered the highest level of offense and the most serious against the public good.

The last layer of government is the federal or national law. This involves offenses legislated by the federal government as criminal behavior (Nemeth 2018). Often this level is relegated to offenses against the federal government or large sections of the populace (e.g., treason, terrorism). However, many federal governments have passed laws regulating individual behavior for offenses that are either especially heinous or which require federal resources to supplement the complex investigations. These include crimes such as child pornography, serious drug crimes (e.g., drug trafficking, sale of illicit street drugs), kidnapping, and bank robbery in the United States because banks are federally insured. White-collar crime and corrupt organizations can likewise invoke federal jurisdiction. These laws are used to investigate and prosecute organized crime rings, such as the mafia and street gangs. The federal laws and law enforcement agencies can also become involved if the crime involves multiple jurisdictions, such as occurs when criminals cross state or provincial lines (Nemeth 2018).

A criminal investigation starts with determining if a crime was committed and then seeking to determine who most likely committed this crime. The evidence that is gathered by the investigator helps to indicate suspicion of a specific person or people. The investigator will usually attempt to determine which individuals had the "means, motive, and opportunity to commit the crime" and to establish the relationships between the victim and any known offenders (Burgess, Roberts, and Rehehr 2009). Often people are victimized by someone they know either intimately or at least moderately.

The type of crime (i.e., crimes against persons, crimes against property, crimes against society) affects the degree of effort and amount of time involved to perform the investigation and typically is consistent with the grading of offenses discussed above (Nemeth 2018). Crimes against persons are defined as crimes in which a specific person has been victimized in the commission of the offense (e.g., criminal homicide, sexual assaults, and robberies). Property crimes, although they do not involve the body or a person being specifically victimized in terms of bodily harm, are nonetheless not victimless. In these crimes it is the property of the victim that is targeted (e.g., theft, embezzlement, burglary). Crimes against society refer to acts that disrupt civil life and/or violate the norms and values of society (e.g., prostitution, illegal gambling, an illegal drug use). The delimitation of these offenses differs in the grading and seriousness of the offense, as well as in the way they are investigated.

The majority of criminal offenses, or suspected criminal offenses, are investigated by a law enforcement agency that is the extension of an executive branch of government (Nemeth 2018). Correspondingly, there are dedicated and trained people possessing the equipment, resources, and training to assist in all aspects of the investigation. However, often these duties fall to private investigative entities (Nemeth 2018). This can occur for a number of reasons. For instance, a law enforcement agency may take the position that there was no offense (or minimal evidence) that violated the criminal code and therefore there is no point in wasting efforts or resources in this pursuit. A victim, family of a victim, or entity may feel otherwise and hire private agents to begin an investigation with the eventual goal of persuading the law enforcement entity that there was a criminal violation. In contrast, a large institution may be the victim of a crime against property that the company

does not want to make public. The company may prefer to have the incident investigated privately so that it may act to remove violators and remedy the situation quietly and without public notice. Once a government agency is involved, paperwork filed through the judicial branch can be publicly available, and the situation may be learned by the news media or those with a specific interest in this entity or its business. This rest of this entry describes various methods used to gather evidence in civil and criminal investigations and explains elements involved in investigations of crimes against persons, crimes against property, and crimes against society performed by a private entity.

Evidence Gathering in Investigations

There are two types of evidence – testimonial and physical – which investigators use to prove or disprove facts in contention. Testimonial evidence involves a statement by a person who is a witness to an act or one that provides information concerning the incident being explored. Examples of this would be an "eye" or "ear" witness to an event related to the incident in question. It could also be a person who was given information by a person under investigation, such as suspect providing a confession. Physical evidence refers to actual things that are collected for review or analysis and provide information to help prove or disprove facts. This includes forensic evidence, like fingerprints, DNA, or toxicology results.

Evidence can also be categorized into direct or circumstantial evidence. Direct evidence directly ties a person to a crime, such as when an eyewitness sees a suspect commit the crime or when fingerprints, recovered from the crime scene, are later identified as belonging to the suspect. Direct evidence produces be clearer link to the suspect than does circumstantial evidence. Circumstantial evidence requires the investigator to draw an inference. For example, a surveillance video shows a suspect going to and/or leaving the area at the time and location at which a crime occurred but does not show the person commit the crime. When circumstantial evidence is used in conjunction with other evidence, it proves to be more conclusive to the jury than when presented alone. A very basic example of the difference between direct and circumstantial evidence can be done with snowfall. If it is snowing in the evening, and then in the morning, there is a fresh coat of snow on the ground, which is direct evidence the snow fell and accumulated overnight. If there was no snow at night and there is snow on the ground in the morning, it can be inferred through this circumstantial evidence that at some point overnight it snowed.

In a criminal investigation in the United States, a jury needs to believe that a crime was committed and that the defendant committed the crime beyond the standard of a reasonable doubt. There are varied legal definitions on reasonable doubt, but their overarching theme is that the jurors do not need to be convinced beyond all doubt. They just need to be convinced beyond a reasonable doubt. This is in contrast with a civil trial where there need only be a preponderance of the evidence. Thus, in civil court, if the side produces 51% of the evidence to support their claim that is enough for a jury to conclude. Criminal trials are held to the higher standard of reasonable doubt for a conviction of a person in trial. The prosecutor bears the burden of proving their case beyond a reasonable doubt, and it is their job to use evidence and witnesses found during the criminal investigation to prove the case to the jury beyond a reasonable doubt. This can be done through a combination of direct and or circumstantial evidence to include witness testimony.

Methods for Gathering Evidence

In this section, the methods for gathering evidence – search warrants, subpoenas, forensic interviewing and interrogation, and technology surveillance – are discussed.

Search Warrants

US society is a democracy based on constitutional rights that value the privacy of the individual (fourth amendment) by preventing a government agent in the investigation of a crime from searching areas that are not open to the public, in

plain view from a public area, or where a person has a reasonable expectation of privacy (Nemeth 2018). This right includes freedom from search in various private locations, such as a person's home, car, technology possessions (phone, laptop, or computers), as well as personal and business bank accounts and records. A law enforcement agent may during the course of an investigation seek the approval of a judge in order to search these areas or obtain private account information through a search warrant if there is probable cause to believe the person committed a crime, search of these locations will result in evidence of the crime, and possessions were used in conjunction to the crime or are pertinent to it (Nemeth 2018). Thus, a judge after reading the warrant and being satisfied that probable cause was appropriately articulated will then sign it. Search warrants are good for specific amounts of time, which vary by jurisdiction, in which the warrant must be executed (Nemeth 2018). In some areas an officer has only 48 h to begin the search, whereas other legislatures allow multiple days before the search warrant needs to be executed or it will expire. A search warrant might be common in a sex assault investigation in which the investigator has probable cause that there is evidence to support the crime in the suspect's residence (Nemeth 2018). The investigator can apply for a search warrant to enter, search for, and seize the evidence as specified in the warrant. Both the locations where they are allowed to search (e.g., suspect's bedroom) and the items they are seeking (e.g., victim's underwear, washcloth used to clean off sperm from victim, used condom) must be specified (Shapiro and Maras 2016). Search warrants can also be used for electronic or online information, such as social media accounts or Internet communication.

Another way information can be obtained is through a subpoena signed by a judge. In this system a judge would sign an order that documents need to be presented to an attorney with an interest in this matter. This can be done by defense and prosecution attorneys and generally is done for trial purposes. In this, most often, it can only be done after criminal charges are filed against an individual. They can require that documents be presented prior to or at the time of trial. Subpoenas requiring documents brought to the trial are often referred to as a duces tecum subpoena. This is in contrast with most subpoenas, which require a person appear in court to provide oral testimony.

Forensic Evidence

After the investigator gets consent from the property owner or a search warrant, then forensic evidence can be gathered. Forensic evidence refers to physical evidence that is collected at the scene or from items at the scene that can, through science, prove or disprove a fact in contention. This physical evidence links the suspect to the crime through contact with the victim, the scene itself, or both. This is often referred to as the *Evidence Linkage Triangle*. The three points of this triangle are the suspect, the victim, and the crime scene, and it is called this term because evidence links these three together. Forensic evidence can also prove elements of a crime. For example, the crime of rape requires penetration. If it is a rape case where penile-vaginal penetration was accused, then a used condom with the suspect's semen on the inside and the victim's DNA on the outside would prove that there was penetration.

Clearly the most probative evidence can specifically identify the perpetrator, but it can both include and exclude in regard to the suspect pool. As Fisher (2004) explained, physical evidence can establish that a crime has been committed or key elements of the crime place the suspect in contact with the victim, scene, or both, establish the identity of associated persons, exonerate the innocent, corroborate the victim's account, and help convince a suspect to confess, and it may be more reliable than an eyewitness. These tasks can be done a variety of ways and through a number of forensic disciplines. For example, fingerprints and footwear impressions provide information about the perpetrator and can help investigators to increase or decrease the suspect list (e.g., eliminate suspects whose prints do not match). Forensic evidence can also link crimes together, which can be very beneficial to an investigator (Nemeth 2018). A serial rapist can leave his DNA at multiple scenes, allowing the

investigator to link rapes from different areas, even if that individual is unknown.

Potentially, the more forensic information gathered at the crime scene, the higher the likelihood that the investigator will be able to use the information to understand known or presumed facts and circumstances of the different cases. The other benefit to forensic evidence is that it can prove facts in contention. Many times, in an investigation, circumstantial information leads to inferences, deductions, and suspicions. Physical evidence, such as a suspect's fingerprints found on an item or in a building, allows the investigator to know the person was in that location or touched that item. This does not solely prove guilt but helps to build evidence in proving it. Other scientific evidence includes bloodstain pattern analysis based on physics and trigonometry (Bevell and Garner 2008). This discipline is defined by subject matter expert Craig Moore as the study of the size, shape, and location of bloodstains in order to determine the physical events which gave rise to their origin. It can provide reliable insight into context and the sequencing of events. Furthermore, it can quickly support or refute claims by involved persons as to what occurred. Forensic evidence can also prove elements of a crime. Rape requires penetration, however slight, as an element of the criminal statute (Nemeth 2018; Shapiro and Maras 2016). If a suspect's spermatozoa are recovered from the vaginal cavity of his victim, then it proves that penetration occurred.

Interview and Interrogation

The purpose of obtaining the subpoena is to compel witnesses to testify in court and to bring documents that are needed as evidence (e.g., phone records) in support the facts of the case (Nemeth 2018). Investigators use interviews to obtain a variety of information from witnesses and victims but rely on interrogations to gain confessions from suspects. Both interviews and interrogations should follow specific guidelines in asking questions, be videotaped, and supplemented by polygraph examination and written statement analyses (Shapiro and Maras 2016).

The evidence obtained through interviewing includes knowledge about the crime itself, identification of a suspect, or even ancillary information about a person, business, or practices leading to the crime. Other information obtained includes insights regarding how the crime was committed, why a person or entity was targeted, and potential motives (Shapiro and Maras 2016). Interviewing can be with a witness, family and friends of a person central to the crime, or with suspects themselves (Shapiro and Maras 2016). If a crime, such as a theft from a business, has a wide array of potential suspects, interviewing can help to narrow the suspect pool and assist the investigator in developing evidence to confirm the correct suspect(s).

Interrogation is similar to an interview, except that the questions are posed to the suspect and focused on the criminal. An interrogation allows an investigator to confront a suspect with the evidence but also allows the suspect to refute this evidence or to explain facts and circumstances around the crime (e.g., mitigating circumstances that may reduce culpability). For example, a driver may have hit and killed a person while speeding but was racing to the hospital with a bleeding child. An interrogation can allow a suspect to confess, that is, to admit guilt and explain the rationale for the crime. Confession is the strongest evidence for an investigator to present in support that the suspect performed the crime. With property crimes, often the perpetrator has a drug addiction and is committing the crimes in order to fuel his or her drug habit.

Technology

Technology is ubiquitous today and offers a number of tools to the investigator. For example, open-source information from the Internet, including social media accounts, can give an investigator great insight into a person's habits, family life, and circle of friends. Another benefit is to reveal information about where a person lives and travels and what is the most important to him or her. A search of telephones, computers, cloud, and other account information to include emails and messaging systems can be highly beneficial to the investigator. Smartphones can be a treasure trove of information, such as location, communication, and photographs that provide time and location,

which could place a suspect at a crime scene, people who served as accomplices, and other sources that could be evidence. This information can help in numerous ways. For example, if conducting a murder investigation, an investigator can determine friends' acquaintances and ways in which the victim spent time from social media in order to determine a suspect pool or perhaps a motive. A person may post information about items for sale that the investigator knows to be stolen. Or, in a sexual assault, a person may send a message or have a dialogue on social media in which admit actual acts or at least place themselves in the area at the time of the incident being investigated. Forensic experts are able to record and use an electronic crime scene with digital and electronic evidence. The rapid technological advancements through the digitalization of data and information is difficult to detect and fragile and requires specifically skilled investigators who keep up with the changes in the field (James et al. 2014).

Another technology tool is the surveillance camera, used both inside and outside businesses as a means to prevent crime but also to help locate perpetrators and provide evidence in criminal prosecution (Nemeth 2018). Most municipalities have cameras to help cover public areas like roadways, parks, and government buildings. Nearly every individual in the United States has a smartphone that would allow the person to record any activity of interest instantaneously. Investigators must use this opportunity to obtain evidence for the cases they are investigating to provide what exactly occurred, who was there, and who committed the offenses. Cameras can show people and vehicles in an area, either before, during, or after an offense – simultaneously capable of providing evidence that a suspect was the culprit but also exonerating a suspect (i.e., prove an alibi).

Image analysis recognition and evaluation are becoming important technology tools to support these investigations by analyzing or enhancing surveillance or other videos (James et al. 2014). These tasks use the familiar Adobe Photoshop (need R) to sophisticated specialized software. This is an ever-developing area of technology with the increase in surveillance video. Face recognition technology is one of these developing areas and is becoming used both in the review of video, as well as in live feeds. Many areas of the country are installing LPR or license plate reading cameras in high-traffic areas to capture license plates and enable law enforcement to identify vehicles used in crimes quickly. Allegheny County District Attorney Steven A. Zappala, Jr. is a leading law enforcement proponent of this technology, and his office has spearheaded and provided funding for LPR cameras not only throughout Allegheny County but also in high-traffic areas of adjoining counties. D.A. Zappala is also advocating to use it to create virtual checkpoints at schools and other areas that may be targets as part of a safeguarding effort. The project currently includes nearly 300 cameras over all with 30% containing LPR technology.

If an investigation includes ongoing activity, such as a string of thefts or even a robbery from a safe, then cameras can be used to surveil the area and to catch the perpetrator committing the crime itself. Microphones can be used to record audio and conversations. The legality of using this technology depends on local laws regarding the use of recording devices, specifically audio recordings. States vary regarding the recording of conversations. In some states it is a felony to surreptitiously record any conversation. Even police cannot record conversations without consent of both parties or an order from a judge. Other states (e.g., NY) allow recording conversation if one party consents, even if the other person is not aware it is being recorded. Investigators need to exercise caution and be familiar with laws anytime they consider employing a recording device as part of an investigation. In the next section, the two types of crime investigations (persons, property) are described.

Crimes Against Persons Investigations

Death Investigations

The most serious crime in society is the taking of a life, so death investigations are paramount when it comes to prosecuting suspects with this criminal violation. A death investigation is multifaceted

and can drain resources, depending on the complexity of the investigation (Nemeth 2018). Hess et al. (2017) outlined important steps an investigator should take in a death investigation. These include assigning multiple detectives, detailed notes at the crime scene, following up on all leads, interviewing all potential witnesses, and attending the autopsy. One of the early steps is an examination of the body, as well as the scene surrounding it. The examination of the body begins with observations noted by detectives or crime scene personnel processing the scene. Here the body is visually examined to make a number of determinations, specifically: (a) estimating an approximate time of death, (b) determining whether the body has been moved, and (c) determining whether there are signs of trauma on any areas of the body.

A time of death is important as it allows the investigators to set a time frame in which to consider likelihood of alibis by various suspects, confirm probability or rule out suspects, and determine which potential witnesses to interview. Witnesses or known persons to the decedent are most likely to help in this process of setting the parameter for time of death estimation, particularly last known time alive, when first discovered, and other elements surrounding the time frame. The rough timetables from these witnesses, as well as other factors such as the temperature of the body, can help to form a rough notion of the time of death, which increases in accuracy when discovery is shortly after death.

If the body has been moved, it is "red flag" suggesting it could be a homicidal death. While there are reasons a body is moved for lawful purposes – such as EMT – first responders rendered first aid/CPR, or police first responders searched for identification. There are a number of things that can help determine if a body has been moved. One such thing is lividity, which is the settling of the blood. In this process, after death, the blood settles by gravity settles to the lowest point. It then becomes fixed in this position on a somewhat consistent timetable. If the lividity is not consistent with the manner in which the body was found, then investigators can extrapolate that the body was moved after the lividity became fixed, that is, postmortem. Rigor mortis is the stiffening of the muscles after death. This also exhibits and then later fades at a somewhat consistent time frame. However, it can be affected by a number of factors too, such as the decedent having a fever prior to death or strenuous activity preceding death. Those factors need to be weighed, but rigor can also alert investigators if a body has been moved prior to rigor mortis setting.

Trauma to the body may be paramount to the investigator determining whether the death was accidental or homicide (Nemeth 2018). It can indicate how the decedent died, as well as circumstances surrounding the events which led to a person's death, and the mechanism that likely caused the death, such as gunshot wounds, stab wounds, blunt force trauma, and something as small as a needle puncture mark in a drug overdose death. After discovery, the body will be taken to a facility, such as a Medical Examiner's Office where an autopsy can be performed by a forensic pathologist. A forensic pathologist is a medical doctor who has continued their training into pathology and later forensic pathology so that they can specialize in determining causes of death with specific training as to injury and other mechanisms of death. It is important to remember that while an investigator at the scene can make observations about injury, the final conclusion is made by the forensic pathologist who is the paramount expert.

Sex Assault Investigations

A sex assault investigation is an umbrella term that incorporates a number of sexual crimes, (e.g., rape), involuntary deviant behavior, domestic violence (e.g., elder abuse, child sexual abuse), and unwanted touching (Nemeth 2018; Shapiro and Maras 2016). These crimes, like death investigations, are multifaceted, and the investigation of the scene is important for collecting forensic evidence. It is important to remember that with the exchange of bodily fluids in a sex assault case, clothing, objects, towels, napkins, used condoms, and the victim's body may all contain forensic evidence (Nemeth 2018; Shapiro and Maras 2016). Child victims should be seen in a child

advocacy center (i.e., a trauma unit with specially trained medical staff), whereas adult victims need to be seen at a hospital that has trained sex assault nurse examiners (SANE) to ensure that potential evidence in or on their bodies is collected (Nemeth 2018; Shapiro and Maras 2016).

A sexual assault is arguably the most devastating experience a person can endure. The investigation is difficult largely because of the psychological damage perpetrated upon the victim, and the stigma of sexual crimes results in shame and guilt feelings by the victim (Shapiro and Maras 2016). As an investigator, it is a difficult and sensitive task to collect the evidence, interview the victim, and prepare for prosecution while preserving the integrity of one's case and the dignity of the victim (Nemeth 2018; Shapiro and Maras 2016). In sexually based crimes, the perpetrator may be a health professional, stranger, friend, acquaintance, spouse, family member, or intimate partner. An investigator must extract every painful detail from the victim in order to proceed effectively, and the victim may later be called upon to repeat this process in court (Nemeth 2018; Shapiro and Maras 2016).

The relationship to the perpetrator is important to establish, and in the vast majority of cases, the victim knows the perpetrator and identifies the person as an intimate partner, friend, or acquaintance (Shapiro and Maras 2016). In these investigations the focus shifts its focus to the collection of evidence that establishes the absence of consent for adults (minors by definition cannot provide legal consent) and/or the presence of force or threat because this tactic may be necessary to counter the perpetrator's defense that the "victim" consented (Minnesota Center Against Violence and Abuse 1998–2005). Investigators should make sure that they are not harboring animosity toward the suspect that may erroneously result in a confirmation bias (i.e., look for evidence of guilt while ignoring exculpatory evidence). The crime of sexual assault, particularly against minors, is considered to be particularly heinous by the public, so investigators should ideally be reasonably sure of the suspect's guilt prior to accusations or the commencement of a criminal prosecution. The consequences of bias are that the investigator is professionally and/or personally ruined from even an allegation if it proves to be false.

There are limitations to investigative capabilities that may hinder evidence gathering. For example, an accused person has no requirement legally to speak with the investigator or even the police, leaving only the victim's testimony as the only evidence (Nemeth 2018; Shapiro and Maras 2016). Additionally, children are not seen as reliable witnesses prior to ages 12–14 years, so often the prosecutor will not proceed unless there is a confession (Shapiro and Maras 2016). Finally, it is unclear whether the sexual assault incident rates are accurate given the self-report research suggesting that many rape incidents go unreported (Shapiro and Maras 2016). The rates of reported and unreported sexual assaults vary due a several factors, such as how the crime is defined, what population is studied, and what methodology is used.

Crimes Against Property Investigations

Crimes against property typically include theft, robbery, and burglary. Theft or stealing is delineated from robbery in that the latter uses force or a threat of force on the victim (Nemeth 2018). If someone steals an item from a store such as in shoplifting, it is a theft. However, if they threaten or assault the clerk in the process (e.g., brandishing a weapon, such as a gun or knife) while demanding money, then it is a robbery (Nemeth 2018). Even if the gun is not real, it is a robbery as there was a threat of force in the eyes of the victim. Robberies and thefts tend to happen quickly, and often there is not much forensic evidence unless a weapon is used, items are touched, or clothing or other items are discarded or dropped during or while fleeing the crime.

A burglary involves entering a building or occupied structure (residential or commercial) for the purpose of commit a crime therein (Nemeth 2018). It is most commonly associated with entering a commercial establishment when is closed or residence and stealing valuables from inside. The underlying crime here is a theft of

property, but it is a burglary because they entered the structure to commit this crime. It is a common myth that residential burglaries most often happen at night while people are sleeping. This is not true, and most burglars only want your valuable and do not want to be confronted or be in a situation of possible violence. Most often, burglars break into businesses at night when they are closed and residences during the day when the occupants are away at work or school. Hess et al. (2017) indicated that burglary has a national average of a 13% clearance rate. This is partially due to it being a common crime, as well as being a crime lacking strong ties between the perpetrator and the victim, resulting in a large suspect pool. This commonality and low clearance rate reinforce the need for a quality preliminary investigation (Hess et al. 2017).

Physical evidence in crimes against property include the items used for the commission of the crime, the stolen property, and biological forensic evidence (e.g., fingerprints, blood, hair, skin). For example, sometimes in burglaries and robberies, the assailants injure themselves and leave their blood at the crime scene. Most property cases are investigated through interviews of the victim and witnesses, interrogations of suspects, and, when possible, surveillance video. In burglaries, thefts, and robberies, an investigator can also attempt to follow the property and locate it if it is sold or offered for sale. This can be tracked through Internet sales or pawnshops. It is easier to track and locate rare, valuable, or otherwise individualized items. For example, a class ring or a watch with an inscription is easier to track than diamond stud earrings that are common and often unremarkable.

Crimes Against Society

Fraud cases often leave a paper or electronic trail. These often use interstate communication devices such as phones, computers, the mail system, or financial and banking institutions (Hess et al. 2017). A specialist such as a forensic accountant may be needed if it was a complex crime such as an embezzlement especially if it occurred over a number of years. In these cases, finding a paper or electronic trail is key to the investigation. The old adage of "follow the money" rings especially true here and can generally point to the person or people perpetrating these crimes. Often this can involve multiple people in key positions where they have access to funds or the ability to cover the trail of the person perpetrating the crime. This may need searches of not just the business accounts but warrant that allow an investigator to access the information for a suspect's private account. In cases where a specific person has been defrauded by another, the "fraud victims are in a good position to provide information regarding the suspects because they had first-hand dealing with the suspects" (Hess et al. 2017).

Conclusion

There are untold number of investigations a year that occur from law enforcement and private security professionals through the United States and the world. These investigations vary from minor offenses of traffic infractions and low-level threat to the most heinous of criminal activity such as rape and murder. It is imperative for these investigations to act quickly but cautiously. Beginning these investigations without delay gives the greatest chance for being able to locate the largest amount of evidence. This includes collecting surveillance videos that will overwrite itself over time, biological evidence like DNA that will degrade or be washed away, as well as evidence that can be intentionally destroyed by a suspect or a party interested in the defense of the suspect. Also, identifying and interviewing those that may have been a witness or have information about the activity should be completed sooner than later. An investigator needs to be cautious that they are examining the evidence from an unbiased perspective that they consider all of the facts and possibilities while they narrow what is possible and who is likely responsible for the illegal acts. The caution also is important in being sure that an investigator does not violate the law in their

pursuit to recover evidence. A government law enforcement official needs to know when they need consent or a search warrant prior to gaining access to an area or item to search for and potentially collect evidence. In the end all of the items and factors need to be weighed in order to draw inferences and determinations in regard to what occurred, if it was a criminal act, and who or whom perpetrated these crimes.

Investigations: Cybercrimes

Michelle D. Miranda
Farmingdale State College, The State University of New York, Farmingdale, NY, USA

Keywords

Cybercrime · Investigation · Digital · Forensics · Crime scene

Definition

Cybercrime investigation: An investigation focused on crimes in which digital technologies were used in the commission of the criminal act.

Digital forensics: A branch of forensic science focused on the scientific analysis of digital devices and their application to matters of legal significance.

Investigation: To observe and study utilizing scientific inquiry, reasoning, and analytical methodologies with the goal of gaining knowledge and understanding about individuals and/or events.

Introduction

Cybercrime is broadly defined as the use of digital technologies in the commission of a crime. These digital technologies may include hardware (computers and peripherals, mobile phones, cameras, storage devices such as thumb drives and hard drives, office equipment such as copiers or scanners, servers, digital home assistants, smart appliances, personal wearable devices, gaming consoles, drones, and myriad devices with a digital component) and software as well as the Internet and related cyberspace (e.g., social media, cloud services, and data transmitted via the Internet of Things). From a forensic perspective, approaching cybercrimes requires consideration of investigative matters; procedural elements including the prosecution and defense of cybercriminals and any related legal matters, such as evidence admissibility and (electronic) discovery; and legislative oversight, which encompasses the legal system's responses to cybercrimes and includes statutes that guide cybercrime investigations and prosecutions (e.g., dealing with matters pertaining to searches and seizures).

Cybercrime investigations include the identification, acquisition, recovery, and safeguarding of electronic traces, as well as any analysis and interpretation of digital data. Data is material which serves as apparent facts as applied to the investigation; raw data may be subject to authentication, analysis, and interpretation and further structured in a systematic manner during the course of an investigation. Cybercrime investigations are guided by several factors, including: the nature or type of crime (e.g., DDoS attacks, child pornography, human trafficking, identity theft, electronic espionage, or cyberterrorism); the type of digital technology recovered or data contained and extracted therein; and the scope of the crime (public/criminal, private [corporate]/civil, transnational/international). Digital traces in a cybercrime investigation are sought to: establish that a crime has been committed; provide location data to support or refute witness statements; develop a timeline of events; or aid in developing patterns in user activity to link criminal behavior. A trace is the remnant of an action, individual, or object in a location or space, and must be decoded and understood to elicit some knowledge about the event (see Margot 2011, p. 91, 2017, p. 32). The examination and interpretation of digital data must be considered in context, and as such, cybercrime investigations incorporate information obtained during the course of the broader investigation, including the recognition and interpretation of physical traces (e.g., fingerprints and DNA), information obtained during witness interviews, and any matters related to standard forensic and police investigation methods into the overall reconstruction of events.

This entry considers three critical components of cybercrime investigations, specifically the physical (or crime scene) investigation, the digital (or laboratory) investigation, and the investigator. Each type of cybercrime will have its own specific investigative approach with respect to procedure and analytical methodology, as will the type of digital technology encountered, but there are general guidelines for cybercrime investigations that establish the foundation of such endeavors. Finally, this entry briefly considers the growing area of scholarship in criminological and psychological approaches to understanding cybercrime.

The Cybercrime and Digital Forensic Investigator

The cybercrime investigator requires general criminal investigation skills as well as specialized knowledge and experience with digital technologies such that the investigator can apply their expertise to a digital, or virtual, environment. The investigator should have formal knowledge and experience in the following:

1. Methods of detection and investigation ("police science"), including interviewing and interrogation. The investigator should be versed in administering investigative interviewing techniques such as the cognitive interview and should be familiar with deception detection.

2. Intelligence analysis. The digital investigator should be able to take their observations and raw digital data ("information") collected during the initial phases of an investigation and be able to extract and interpret the most relevant data to produce a meaningful assessment and interpretation ("intelligence").
3. Analytical reasoning skills. The investigator should be able to begin their scientific methodology by asking the right questions in order to define the scope of their investigation. This method should include the utilization of abductive, inductive, and deductive reasoning to form meaningful hypotheses and adapt lines of inquiry as they progress through their analysis. Investigators should be able to identify relationships and patterns in the data and should be aware of cognitive biases or analytical variation that may warrant control measures or calculations of error.
4. Technical and scientific knowledge about digital traces and the interrelationship between digital and physical traces. The investigator should be able to recognize and handle digital traces and related devices so as to minimize loss and damage while maintaining the integrity of the digital media. Recognition and handling of traces are critical aspects of an investigation and may often be the most important factors in a case. In addition to the general volatility of digital traces, handling digital traces may vary depending on the status of the device at the time it is first encountered. The investigator should have knowledge of peripheral and associated devices when collecting digital technology, whether it be a media card or a power cord. Furthermore, the investigator should also have knowledge about whether or not a device requires an uninterrupted or continuous source of power. For example, the handling and packaging of a mobile device requires consideration of whether it is discovered on or off, whether it is locked or unlocked, whether or not it is actively connected to a network, and whether or not it exhibits signs of attempted destruction or damage (e.g., smashed or submerged in a liquid). The investigator should be aware of the nature of any digital and electronic media, including the location of unique identifiers (serial numbers), how to repair a device in the event that there is physical damage, and general information regarding default or standard operating systems for a given device. Knowledge of anti-forensics has also become a critical aspect of digital investigations and must be part of the digital investigators skill set. Finally, the investigator should be aware of the potential for physical traces such as fingerprints or biological traces (e.g., a blood or saliva stain that may be submitted for DNA analysis). Awareness of such traces should include the ability to acknowledge the potential for such traces to be present on a digital device as well as the ability to properly secure, package, and store the digital device to preserve and maintain the integrity of both the digital and physical traces for further analysis;
5. Legal and procedural requirements (for domestic and international investigations and prosecutions), both general and specific to digital evidence. Such knowledge includes matters pertaining to privacy; search and seizure; rules of evidence (admissibility); internal policies and procedures such as those that may be in place within corporations and government agencies; policies and contracts such as those that may be administered by third-party service providers; challenges to international investigations (including technical matters such as criminal enterprise, sophistication and technology; jurisdictional matters such as state sovereignty; and legal matters such as agreements, procedural requirements for requesting legal assistance, evidence acquisition, extradition policies, and any limitations to existing practices).

With respect to stored electronic communications and general content data, Brown (2015) provides a useful overview of service providers and avenues of inquiry for investigations (69). Brown further weighs in on the "human side of a cybercrime inquiry which is pivotal for giving meaning and weighing significance" to digital traces, providing a list of desired skills and related competencies of an investigator (2015, p. 64). These

include experience and what Brown divided into general, "soft" digital forensics investigative skills and technical, "hard" digital forensics investigative skills (2015, pp. 65–66). Brown's soft investigative skills include communication, collaboration, and rationality, while the hard investigative skills include structured, unstructured, and semi-structured data analysis, reverse engineering, programming and scripting, and virtualization. INTERPOL (2019) also developed a "non-exhaustive skillset checklist," which lists data recovery, computer forensics, mobile phone forensics, network forensics, audio, video, and image forensics, and emerging technologies forensics (e.g., Internet of Things forensics) as necessary analytical skills (58–59).

Physical [Crime Scene] Investigation

Crime scene investigation contributes to the fact-finding objective of an investigation and does so by aiding in identification and reconstruction. Described by De Forest (2005) as a recording medium, the crime scene can aid in establishing links between the event, the perpetrator, and the victim by way of physical and digital traces left behind. Digital traces may include documents and records, photographs and digital images, audio and video recordings, and geolocation data, as well as digital devices that may serve as secondary crime scenes containing additional digital traces in a virtual environment. It is important here to distinguish crime scene processing and crime scene investigation. The former, crime scene processing, is a "bag and tag" operation to be conducted by a technician, while the latter, crime scene investigation, is a scientific endeavor of recognizing traces, whether physical or digital, and applying the scientific methodology and analytical reasoning that will lead to a meaningful reconstruction that can further contribute to the cybercrime investigation. De Forest (2005) highlights the need for educated, experienced scientists at the crime scene, and this idea can be extended to the need for individuals with added digital expertise at crime scenes dealing with cybercrimes and digital forensic investigations.

Crime scene investigation is characterized by utilization of a scientific and methodical approach, which includes observation, analytical reasoning, and iterations of developing and modifying hypotheses as new observations are made and data is acquired, whether the data results from laboratory analysis of the physical and digital traces or from "traditional" investigatory methods including witness statements during investigative interviewing. Investigators should be aware of cognitive biases and fallacies in their reasoning and account for such in their investigative process.

Recognition and identification of digital traces is not isolated to the immediate crime scene but also includes assessing the scene and its surroundings for CCTV footage, digital images from mobile devices, social media posts, and access control technologies. Investigations may also include evaluating historical and archived digital media in the form of records, images, and videos. In addition, investigations may include thorough observation, examination, and analysis of a scene for comparison to earlier video footage, photographic materials, audio recordings, or geolocation data at the same location in an effort to establish links and reconstruct a plausible sequence of events.

The act of "processing" the physical crime scene involves collecting, packaging, transporting, storing, and documenting traces identified within the scene. Collection and packaging require consideration of the nature of the evidence, including the presence of adhering physical traces. Care must be taken to prevent loss or destruction of digital and physical traces during handling and packaging. Specialized packaging may be necessary for digital devices and may include the utilization of Faraday bags, anti-static bags, or any alternate electromagnetic radiation-blocking containers. Documentation should be contiguous and detailed, and should include notes and photographs. Records should be kept to maintain chain of custody and unique identifiers should be utilized for each item recovered.

It may be necessary to evaluate digital devices at the scene and determine whether or not they should be recovered for analysis in the laboratory or whether they should be examined in the field

for purposes of extracting data. Such field examinations may be conducted in an effort to save time or reduce the number of items submitted to the laboratory, especially in those circumstances where there is a large amount of digital data known to be of no significance to the investigation, or in cases where there are minimal resources allocated for digital investigations within the laboratory (e.g., lack of trained analysts/investigators and equipment). With respect to determining the feasibility of onsite versus offsite searches, Maras (2015) notes the following factors: the configuration of the hardware or software, the overall size and complexity of the system, and the technical demands of the search (35). In general, investigators responding to the scene should at least be able to properly process the devices (collection, packaging, transport, storage, and documentation as described above) to prevent loss or damage and ensure the integrity of the items recovered and the traces therein. When in doubt, data extraction or recovery should not be attempted by inexperienced individuals at the scene and should instead be conducted in the laboratory by experienced digital analysts/investigators.

Digital [Laboratory] Investigation

Laboratory analysis of digital traces during a cybercrime investigation should be marked by analytical integrity by way of chain of custody and record maintenance, standard operating procedures, and functional autonomy through quality assurance and method/tool/instrument validation. Procedures should be developed such that they are scientifically robust (e.g., transparent and reproducible) and allow for analyst/investigator flexibility should their findings result in alternate lines of inquiry. According to the International Organization for Standardization (ISO), "The incident under investigation should be clearly identified and defined, including limitations to the scope of the investigation. Sources of potential digital [traces] and questions to be answered should be identified. Sources of risk and their potential effects on the investigation, personnel, and systems should also be identified" (ISO/IEC 27041: 2015a, p. 6).

Various investigation process models have been developed as a means of providing a step-by-step approach to digital investigations since the first digital forensics research conference approached the topic in 2001. One result of the conference was the development of a process model for digital forensic investigations, which was included in a technical report entitled *A Road Map for Digital Forensic Research*. Workshop attendees produced a linear process consisting of Identification→ Preservation→ Collection→ Examination→ Analysis→ Presentation→ Decision (Palmer 2001, p. 17). There have been myriad proposed models since 2001, which are largely assessments and reiterations of the same core steps (planning/preparation; scene processing; data acquisition/analysis; reporting/presentation). In 2008, Carroll et al. (2008) developed a *Digital Forensic Analysis Methodology* flowchart in an effort to contribute to the early development of a digital investigative method. This flowchart highlights three major parts of the process: preparation/extraction, identification, and analysis. In their flowchart, Carrol et al. pose a series of specific "Who, What, Where, When, How and Other" questions to guide the investigator during the analysis phase. In the same year, Marcella and Menendez (2008) presented "a structured approach to cyber forensic investigations" with a *Flowchart for the seizure of electronic evidence and associated internal control questions* (193).

After numerous process model iterations, ISO released in 2015 a "harmonized digital investigation model" in the form of a flowchart depicting a series of processes and associated subprocesses (ISO/IEC 27043: 2015b, p. vi). The primary processes include readiness, initialization, acquisitive, investigative, and concurrent, with the acquisitive and investigative stages consisting of the bulk of the analytical portions of a digital investigation. The acquisitive process deals with the physical (crime scene) investigation of a case in which digital traces are identified, collected, and acquired. The identification and collection subprocesses as

presented would be equivalent to the identification/recognition and processing discussed above. The acquisition subprocess within the acquisitive stage is described as "optional," for the reasons noted above regarding evaluating onsite versus offsite data acquisition. The investigative process deals with the acquisition, examination, analysis, and interpretation of digital traces. With respect to interpretation, the document asserts, "One goal of the digital evidence interpretation process is to use scientifically proven methods to construct explanations for the presence of the digital artefacts identified. . .within the context of the investigation. If the contextual information changes, the interpretation may also have to change in order to reflect" such changes (ISO/IEC 27041: 2015a, p. 19). More recently, INTERPOL (2019) presented a series of flowcharts addressing the acquisition process, computer examinations, and a process of analyzing [an] exhibit's artifacts (68–70).

Proceeding with analysis requires knowledge about the nature (type) of the recovered media and consideration of the data to be recovered. Such considerations may include accessibility: direct access (to data such as documents, photos, videos, emails, internet browser history, specialized software, programs or applications, social media, peer-to-peer files, log files, stored data), remote access/analysis, and stored v. real-time data (subscriber data, traffic data, and content data; see UNODC 2013, p. 123). After making such assessments, the analyst/investigator can move forward with selection of the analytical tool that should be employed. Selection and utilization of specific tools is critical for guiding decision-making and hypothesis testing, including the selection and order of subsequent analytical procedures. Considerations should include specification, performance capabilities, reliability, search or analytical parameters, and limitations (potential for errors). The latter consideration requires the analyst/investigator is knowledgeable about detecting and troubleshooting such errors and inconsistencies (manual intervention), conducting risk assessments, and reporting any error estimates or statistically significant deviations. In general, the tools employed and the analytical methods used should be validated and documented: "Before using a preferred tool or method to conduct an investigation the investigators should consider the likely effects of all the weaknesses of the complete process sequence selected. A formal understanding of the weakness of a process enables theses errors to be effectively controlled through the use of correct process selection and robust documented risk analysis or assessments" (ISO/IEC 27041: 2015a, p. 8).

The acquisition, or retrieval, stage of a digital investigation is often akin to a secondary crime scene investigation and must consider the elements of digital trace recognition and collection. Acquisition may be direct or remote. Direct acquisition is marked by drive imaging and content duplication (copying) and recovery of data, which requires consideration of operating systems and configurations, the amount of data, and whether there will be dead (no power) v. live (actively running) system acquisition (see INTERPOL 2019, p. 32). For dead systems, INTERPOL advises considering the following: active files, deleted files, file slack, partition slack, disk slack, and shadow files; device artifacts, operating system files, file registry, file metadata, encrypted files, log files, and database files; browsing history, e-mail, social media, and peer-to-peer file sharing (INTERPOL 2019, p. 41). For live systems, INTERPOL advises considering the following: random access memory, running processes, network connections, system settings, storage media, and cloud storage (INTERPOL 2019, p. 42). Further considerations include locating deleted, hidden, encrypted, password protected, or otherwise concealed or manipulated data (steganography, cryptography). Additional analytical steps include searching, sorting and filtering data, which involves identifying space (slack, unallocated) and partitions; and the recovery or extraction of data. INTERPOL further describes logical extraction (accessible storage media) and manual extraction (inaccessible storage media as a result of electronic or mechanical failure) of data as well as data isolation techniques (manual methods, wireless jamming, Faraday shielding; see INTERPOL 2019, p. 35, 37).

"The opportunity for recovery of digital [traces] will depend on many factors, including

the volatility of the original data to be acquired, the age and condition of the item submitted, automatic system deletion of unallocated data and the level of security features applied by the original user" (ENFSI 2015, p. 32). Each analytical step requires an element of human assessment and problem-solving on the part of the examiner/investigator. The analytical process may be iterative based on the nature of recovered digital traces. The data recovered is subject to interpretation, in which the investigator will consider the significance of the data and transform the information into intelligence. The data and any interpretations can be applied to a reconstruction of events to determine locations and transmission of information and develop a sequence of actions.

A critical component of data analysis is authentication. It is important to verify data integrity (e.g., by way of identification of digital hash values) and overall continuity of the data, and in many cases, assign attribution, authorship, and ownership to digital devices and the traces therein. The UNODC (2013) notes that, "the party offering the evidence must demonstrate that the digital information obtained from the device is a true and accurate representation of the original data contained on the device ('authenticity') and that the device and data sought to be introduced as evidence is the same as that which was originally discovered and subsequently taken into custody ('integrity')" (158). The investigator should keep in mind that authentication can be supported or refuted by "traditional" investigatory methods and supplemental physical traces.

Network investigations may result as a response to intrusions, attacks, or suspected cyberterrorism. Such investigations require specialized knowledge of network security tools and access control methods in a virtual environment. Network investigations may involve surveillance and monitoring in real time or live time, obtaining traces from an active device or intercepting communications utilizing hardware, a virus, or a keystroke logger. In addition, in cases of high volumes of data, the analyst/investigator must be able to filter data during the analytical process and look for patterns within the data. Network investigations may also involve criminal or geographical profiling techniques to identify perpetrators or locations. As with direct analysis on recovered digital devices, data integrity and the utilization of robust methods are of critical importance.

Criminological and Psychological Considerations

Two areas of cybercrime investigation gaining attention and scholarship are cybercriminology and the psychological assessment (behavioral analysis) of cybercriminals for purposes of offender profiling. Cybercriminology presents a criminological approach to understanding cybercrime, the cybercriminal, and the victim (victimology; cybervictimization). Maras (2017) asserts, "cybercriminology tests the applicability of mainstream criminological theories to cybercrimes committed. . . [and] seeks to shed light on the nature and extent of cybercrime, assess reactions to cybercrime and the implications of these reactions, and evaluate the efficacy of existing methods use in the control, mitigation, and prevention of cybercrime" (13).

Behavioral analysis during the course of a cybercrime investigation can aid in reducing the number of possible suspects, determining the motive behind a cybercriminal's activities, tracking a suspect, identifying associates in a criminal enterprise, and in some instances, identifying the perpetrator(s) of the cybercrime. With respect to the latter, identification can be facilitated by assessment of the type of attack and the target, the skill level of the attacker, and stylistics (see, for example Steel 2014). Forensic stylistics is the examination of style in [written] language including grammar, syntax, spelling, vocabulary, and phraseology for the purpose for resolving questions related to disputed authorship or meaning (Kingston and Stalker 2006, p. 95). Casey (2006) notes, "the basic concept underlying behavioral evidence analysis is simple—offenders leave an imprint of themselves at the crime scene, and their actions and communications tell us something about the individual" (58). Linguistic surveillance can be utilized to aid in the identification of the perpetrator, and can also be useful for threat

assessments to measure perpetrator credibility and seriousness of the crime during a cybercrime investigation.

Conclusion

Taking on digital investigations requires balancing digital knowledge and investigative experience. Goodison et al. (2015) conducted a needs assessment and identified problems on both front end (crime scene) investigations and back end (laboratory) investigations ranging from deficiencies in personnel, funding, tools, and technologies to challenges in accessing and analyzing specific types of devices and data therein. One noted challenge involves first responding officers to an incident or arrest that do not know how to properly recognize or secure digital devices. Proposed solutions include providing general training focused in the identification and processing of digital devices and traces at crime scenes for police academy recruits, training recruits in law and cybercrime, and specific training focused in advanced digital investigations to those individuals in an investigatory (detective) track (see, for example, proposed solutions applied to the recovery and analysis of digital evidence in sexual violence investigations presented by Maras and Miranda 2017). Such training would be similar to the training recruits and detectives receive presently on the subjects of physical traces and DNA. Another noted challenge is that analysts and investigators must maintain current with respect to the recognition, collection, preservation, and analysis of new and evolving digital technologies, as well as the anti-forensics efforts developed to hinder such investigative endeavors. One proposed solution is certification and continuing education for digital forensic investigators. Both the development of programs for effective education and training of digital investigators and the development of standard investigative methods of conducting digital forensic investigations are underway to meet the increasing number and types of cybercrimes encountered in both the public and private sector. Due to the transnational nature of cybercrimes and the increased sophistication of cybercriminals and technologies, the utilization of tools such as behavioral profiling may prove useful for identifying the cybercriminal based on their motivations and methodologies. The application of criminological and psychological approaches to cybercrime can thus enrich cybercrime investigation processes.

Definition

Domestic investigation: the process by which a private investigator collects information to support a client's position in a family or relationship matter, typically concerning at-fault divorce, disputes over marital assets, or child custody arrangements.

Introduction

The stereotype of the private investigator as a disreputable sleuth for hire who catches cheating spouses is still widely held, although it obscures the complicated reality of domestic investigations. While a proportion of private investigators still specialize in these investigations, they now constitute a relatively small proportion of the work undertaken in the private investigation industry (Faber 2013). Furthermore, domestic investigations frequently concern a range of issues outside of infidelity and are overwhelmingly undertaken in a professional and lawful manner to inform legal proceedings around divorce-related disputes (Prenzler 2006). Critically, delving into the private lives of clients and their families is uniquely difficult for private investigators and can intensify already emotionally heightened disputes. Changes to family law systems across the United States and other Western countries regarding marriage and divorce, and the proliferation of certain personal and Internet technologies, have also had implications for the nature and frequency of domestic investigations. This chapter will begin with a brief overview of domestic investigations, before outlining the investigative process and the types of evidence commonly collected. It concludes with a discussion of some of the unique challenges that private investigators regularly encounter when undertaking these investigations, including the emotional nature of this work, the ethical and practical dilemmas inherent to domestic investigations outside of legal proceedings, and the emergence of new technologies.

What Are Domestic Investigations?

The main task for private investigators when undertaking a domestic investigation is to search for and collect information on misconduct or mistreatment within a client's family or marital relationship (Becnel 2017; Gill and Hart 1996; Gill et al. 1996; McMahon 2007; Prenzler 2006). Much of the investigation work undertaken by private investigators throughout the early- to mid-twentieth century focused on uncovering spousal infidelity. This was largely driven by laws at the time requiring spouses to demonstrate some form of marital misconduct or mistreatment in order to obtain a divorce, which frequently amounted to establishing the existence of an extramarital relationship.

From the 1970s, family law systems across the United States and other Western countries gradually introduced options for no-fault divorce, removing the need to demonstrate spousal misconduct or mistreatment (including infidelity) and allowing couples to legally end their marriage when they decide it is no longer worth continuing. Consequently, the demand for domestic investigations focused on infidelity reduced significantly in many Western countries, and less than 5% of private investigators in the United States now specialize in undertaking these investigations (Faber 2013; Gill and Hart 1996, 1997; although evidence suggests that there have been recent increases in demand for domestic investigations of this nature in China and South Korea as social taboos around divorce have subsided, see Jeffreys 2010; Lee et al. 2014). However, although no-fault divorce has become standard, reducing the need for divorce-related domestic investigations, private investigators are still sometimes engaged when at-fault divorce is pursued. While infidelity continues to be the focus of most of these divorce-related investigations, they can also concentrate on uncovering evidence for other forms of marital misconduct and mistreatment, including physical and psychological abuse, or spousal abandonment.

Aside from infidelity and marital misconduct and mistreatment, private investigators are also hired during divorce matters where there is a dispute over marital assets. In these cases, a domestic investigation will focus on uncovering income or other assets concealed by a spouse to prevent their fair distribution across both parties or to avoid paying alimony or child support. Finally, domestic investigations can be initiated where there is a dispute regarding child custody, and a client wants information to demonstrate their former spouse's lack of fitness as a parent.

The goal of a domestic investigation across these different types of matters is to generate evidence that can be used by a client during a legal proceeding, either to ensure a fair distribution of marital assets or to obtain primary or sole custody of children. Importantly, evidence of infidelity and other forms of marital misconduct and mistreatment is now used during at-fault divorce proceedings to support clients who are pushing for more alimony or a larger share of the marital assets, and not to justify the divorce.

While private investigators may be hired to undertake a domestic investigation directly by someone undergoing a divorce-related or child custody dispute, they are more often hired by, and liaise with, the attorneys representing these individuals. As domestic investigations are rarely straightforward, private investigators typically charge hourly rates to undertake them, ranging from US$40 to $200 per hour (PInow 2019). Often this will not include additional costs incurred such as equipment fees (e.g., photos and videos, GPS equipment) and travel and accommodation costs, which clients pay as a flat fee. Clients typically pay a retainer prior to a domestic investigation commencing, and hourly rates and other costs are charged against this, with anything left at the conclusion of an investigation being refunded. The total cost of these investigations varies widely, ranging from around US$300 to over US$1000, while clients can pay retainers of up to US$5000.

The Process of Domestic Investigations

How a domestic investigation is undertaken, and what evidence is collected, will naturally depend on the nature of the matter being investigated (Becnel 2017; McMahon 2007; Nemeth 2010;

Schefcick 2004). Nevertheless, there are a number of investigative techniques that are commonly used as part of these investigations, and they invariably culminate in a brief of evidence comprising critical documents, visual records, interview transcripts, testimonies, and/or investigator reports for use in a legal proceeding.

As in any private investigative work, interviews are often used during domestic investigations (Becnel 2017; McMahon 2007; Nemeth 2010; Schefcick 2004). Interviews with clients in the earliest stages of an investigation are important for establishing the parameters and focus of an investigation (i.e., what the target is suspected by the client of having done and why they suspect it) and for obtaining details and lead on the target that will facilitate further investigative activity. Private investigators may also interview a target's colleagues, associates, and neighbors to obtain investigative leads, while domestic investigations pertaining to child custody disputes often involve investigators speaking with children's teachers and carers. Finally, witnesses to marital mistreatment or misconduct and/or poor parenting practices can be very useful sources of information during these investigations. Aside from establishing the scope of a domestic investigation and providing leads, transcribed interviews and written statements can also form crucial pieces of evidence, both on their own and as supplements to other forms of evidence.

Physical surveillance is regularly undertaken, particularly as part of investigations pertaining to at-fault divorce proceedings and child custody disputes (Becnel 2017; Jeffreys 2010; McMahon 2007; Nemeth 2010; Prenzler and King 2002; Shulman 2000). The goal of surveillance will generally be to observe and record (usually visual) evidence of certain activities engaged in by a spouse, most often infidelity, abuse, or practices that reflect negatively on their fitness as a parent. Preparation is critical before undertaking surveillance. Investigators must know what their target looks like and obtain detailed information on physical characteristics (e.g., hair type and color, eye color, size and physical build, tattoos, and other distinguishing features) and mannerisms prior to commencing any surveillance activity. Other information, such as the target's address, vehicle details, place of employment and other frequented locations, and known associates, is also vital to becoming familiar with likely surveillance sites and paths in advance of actual field work. When infidelity is the focus of investigation, uncovering details of the person with whom a spouse is suspected of having extramarital relations will also aid in the surveillance process, particularly in identifying likely liaison sites and times. Mobile surveillance may be undertaken initially, as an investigator is becoming familiar with the sites and paths frequented by a target and activities performed at these sites. Later, an investigator may undertake a fixed surveillance at a few select locations where she/he believes there is a high probability of obtaining evidence. Importantly, as the information being collected will often be used as evidence during a legal proceeding, its collection and storage must be thorough. Visual evidence must be as clear and unambiguous as possible in whom and what it is showing, and accompanying notes must be detailed.

Reviews of official documents and records are also commonly undertaken as part of domestic investigations (Becnel 2017; McMahon 2007; Schefcick 2004; Shulman 2000). Document reviews are critical to identifying income or assets that have been concealed by a spouse during divorce proceedings and conducting background and character checks on parents to inform assessments of each person's suitability as a custodial parent. Vast amounts of information relevant to these goals can be obtained through document reviews, including full names and dates of birth, social security numbers, education and employment details, possible relatives, current and prior residential addresses, vehicle registrations, voter registrations, business and commercial affiliations, property ownership, credit history, organizational membership, criminal convictions, traffic offenses, and permits held. Much of this data is freely available to the public and can be accessed online or on-site in public libraries, government offices, court houses, and some private sector organizations. Even the target's trash can contain documents useful to these investigations. This information is now also collated in online

subscription investigative databases, allowing private investigators to obtain documents and records from a variety of different sources without having to expend as much time or effort. Of course, as in any investigation that involves collecting documentary information, investigators need to demonstrate its accuracy and verifiability, along with the reliability of its sources.

The Challenges of Domestic Investigations

Domestic investigations can present private investigators with a number of unique practical, ethical, and emotional challenges. Private investigators have noted that domestic investigations can be highly emotional, given their focus on disputes that have serious implications for clients' financial and personal lives (Gill and Hart 1997; McMahon 2007). Many have also noted the risk of clients refusing to accept the outcome of a domestic investigation where findings are not supportive of their predetermined positions. Under these circumstances, it can be difficult for private investigators to remain objective and refrain from becoming emotionally involved in a case. Furthermore, they may feel pressure to violate the law and other ethical/professional standards to collect evidence and push for an outcome they know their client wants (e.g., generating evidence of infidelity through entrapment).

Additionally, private investigators are sometimes asked to undertake domestic investigations outside the scope of those discussed in this chapter. These include background checks on potential suitors a client is dating, investigations of infidelity in nonmarital relationships, and checking for drug use or other misbehaviors by clients' children (Prenzler 2006). Critically, while not illegal, some private investigators consider these investigations in breach of their professional codes of conduct and refuse to undertake them, as they do not inform a legal proceeding of any kind and involve invading an individual's privacy purely to satisfy a client's personal curiosity (Becnel 2017). Given the occurrence of these investigations outside of any formal legal proceeding, there is also much more ambiguity around the standard of proof that must be met for a client's suspicions to be considered supported.

Finally, new technologies have introduced a number of challenges, but also opportunities, for private investigators undertaking domestic investigations. As discussed, the growth of the Internet has brought with it a proliferation of databases that collate personal information from various sources that investigators would previously have had to locate and search manually. This has greatly reduced the time and effort required by private investigators to undertake domestic investigations, particularly those concerning disputes over marital assets, but carries with it the need to carefully discern reliable and up-to-date databases from those with less reliable or outdated information. Additionally, the proliferation of mobile phone technology and social media in particular has presented private investigators undertaking investigations into infidelity and other relationship issues with a wealth of potential information and leads, including records of conversations, photographic/video evidence, and social connections.

Conclusion

This chapter has examined domestic investigations, which private investigators undertake to inform legal proceedings regarding at-fault divorce and legal disputes over marital assets or child custody arrangements. Changes to divorce laws since the 1970s, specifically the introduction of no-fault divorce, have greatly reduced the demand for these investigations in the United States and other Western countries, although they remain the specialty of a small proportion of private investigators and continue to play an important role in the outcome of some divorce-related legal proceedings. Many of the investigative techniques and information sources used by private investigators as part of other types of investigations (i.e., interviews, physical surveillance, and document reviews) are employed when undertaking domestic investigations. Importantly, domestic investigations frequently require private investigators to navigate a number of unique

practical, ethical, and emotional challenges. These include the painful and distressing nature of what is typically investigated (e.g., infidelity, abuse) and of the potential implications of these investigations for clients (e.g., loss of child custody), requests to undertake investigations outside of formal legal proceeding, and the proliferation of certain information technologies, which have created both challenges and opportunities for private investigators.

Investigations: Employee Theft of Employer Property

Clarissa Meerts
Faculty of Law, Department of Criminal Justice and Criminology, Vrije Universiteit Amsterdam, Amsterdam, The Netherlands

Keywords

Asset misappropriation · Employee theft · Internal investigations · Corporate investigations

Definition

Stealing, Use or misuse of an employer's property or assets by an employee without permission.

Introduction

Employee theft of employer property is a major issue for organizations (see, e.g., a 2017 article on. com, claiming a 50 billion loss per year for US businesses). Even though the general scope of the problem seems apparent, exact numbers of

employee theft are difficult to obtain. The dark number for employee theft is high. One reason for this is the fact that much employee theft goes undetected or is erroneously defined as another loss (▶ Retail Shrink). It may, for example, be unclear whether an item is stolen or just lost and if stolen, whether it was stolen by an employee or a customer (▶ Consumer Retail Shoplifting). Another reason, however, is that many employers decide not to report the theft to the police, investigating the matter themselves instead (Meerts 2018b). This contribution starts with a discussion of the issue of employee theft, after which investigations into employee theft are discussed.

Employee Theft: Definitions and Types

As mentioned above, theft of employer property by their employees is a major issue for organizations. "Theft" or "asset misappropriation" can be defined in a narrow and a broad way. In its yearly "report on the nations," the Association for Certified Fraud Examiners (ACFE) divides asset misappropriation into the general categories "cash" and "inventory and all other assets" (2018: 11). Under the banner of asset misappropriation of "inventory and all other assets," one can place both tangible and non-tangible assets. In a narrow definition, theft is about the misappropriation of tangible property. In a broader definition, employee theft also includes non-tangible assets, such as money stored on a bank account or even time. Other forms of employee crime, such as workplace violence, employee theft of employee property, or corruption/bribery, are not within the scope of this contribution but may be very harmful to an organization and individual victims nonetheless.

The theft of tangible objects may be small-scale and low-impact (e.g., in the case of employees occasionally taking office supplies such as stationary home) but may also involve large-scale theft, theft of very valuable property (e.g., laptops), or theft of (large amounts of) cash. Theft of employer property is, however, just one of the multiple ways in which an employee may enrich himself or herself at the detriment of the employer. Another common form of employee theft is asset misappropriation in the sense of fraud or embezzlement. This type of employee theft is concerned with the theft of an organization's assets by people who are entrusted with the management of such assets. Strictly speaking, theft of cash from a cash register and fraud through false reimbursement fall under the banner of asset misappropriation. However, the most damage is done when asset misappropriation concerns the theft of money through virtual cash flows. This last type includes famous examples of rogue traders, e.g., Nick Leeson (Leeson and Whitley 1996), accounting fraud, e.g., Enron (McLean and Elkind 2013), and embezzlement, e.g., Bernie Madoff (Van de Bunt 2010).

Another manner in which employees may commit theft against their employer is theft of "time" or of services. In such a case, services provided by the employer or the time for which the employer pays is used inappropriately. This may be through the falsification of billable hours (stating more hours were worked than was the case in actuality), or the employee may, for example, use company time for personal activities. Many employees, for example, use social media at work, but this also includes behavior that is commonly considered inappropriate, e.g., watching porn at work. In case of "theft of time," the line between employee *crime* and behavior that is *undesirable* but not criminal gets blurry (more on this below).

Another harmful form of employee theft of employer property is the theft of ideas. Through, for example, corporate espionage, intellectual property might be stolen by employees, selling it to competitors or even states. This type of employee theft often causes much damage.

Employee Theft: Perpetrators

Employee theft may be committed by employees from all levels of an organization. Lower-level employees and middle and upper management are all involved in different types of employee theft of employer property. The type of theft and the damage caused by it depend on the position of the employee (ACFE 2018). The well-known saying "opportunity makes the thief" is relevant in this context. Theft of cash is more

likely in the case of those employees who handle cash (cashiers, lower management), while misappropriation of "virtual" assets can only be done by employees (often managers) who are in a position to sign off on financial decisions. It has been suggested that the response to the instance of employee theft is dependent on the position of the employee within the organization as well: in case of lower-level employees, organizations tend to more often report officially to the police than when it comes to employees who have a higher (and, importantly, more sensitive) position within the organization (Meerts and Dorn 2009). We now turn to these reactions to employee theft.

Investigations into Employee Theft: Public or Private?

The security landscape can be divided into different security providers (see also ► "Police: Public Versus Private Policing"). Security may be provided by the state (► Public Policing), by private security providers or by public/private partnerships (see ► Security: Concepts and Definitions). Investigations into theft of employer property are in many cases not executed by the criminal justice system (Button et al. 2015). For several reasons, organizations tend to not report internal crime to the police (Williams 2005; Meerts 2018b). For one, reporting to law enforcement authorities inevitably leads to a loss of control over information flows and over the process of the investigations. Criminal investigations can do much damage to the reputation and to the day-to-day processes of an organization. Secondly, criminal justice investigations often do not lead to an outcome that is very useful for an organization. Many reports by organizations to the police are not investigated, and further along the line in the criminal justice system, the prosecution office might decide not to prosecute, or a judge might not deem guilt proven. But even if a case is investigated and prosecuted and a guilty party is punished, the punishment that follows will not solve the problem of the organization. The employee is not fired by a criminal prosecution, and the stolen assets are often not recovered and returned to the organization. Furthermore, criminal justice solutions are notoriously slow. All of this makes a report to the police quite an inefficient step from the organization's point of view. Relatedly, there is a low level of confidence among organizations with regard to the problem-solving capabilities of the criminal justice system. A final reason for organizations not to report is that the criminal justice system only deals with a limited scope of behaviors: only those that fall within the reach of criminal law may be investigated and prosecuted through the criminal justice system. This means that those types of employee misbehavior that are undesirable but not criminal cannot be reported to the law enforcement authorities.

The above considerations lead to the situation in which many instances of employee theft are not reported to, or investigated by, law enforcement authorities. Instead, organizations often investigate employee theft or fraud themselves (through their in-house security department) or contract corporate investigators to do so (Meerts 2018a). These (internal or external) corporate investigators do not have powers of investigation, available to the police, but their position to the organization gives them much access to information within the company. As an employer, the organization has access to much information about their employees. This means that corporate investigators can use information derived from internal systems (including communication systems such as email), internal documents (such as financial administration), and open sources (such as the Internet). Even though corporate investigators do not have the legal power to interrogate an employee, they may interview him or her, and although an employee's cooperation is voluntary, the employer may attach consequences (such as dismissal) to noncooperation.

Many instances of employee misconduct are thus investigated privately (Gill 2013). After such an investigation, a report to the authorities may still be made; however, many employers opt for a private solution (Button et al. 2015). Solutions can be sought within the private legal sphere in numerous ways. Employee theft of employer property may be settled in civil court, through a civil suit to reclaim damages or to terminate the labor agreement. Additionally, the labor contract may be ended through the use of

employment regulations, and internal regulations can be used to discipline the employee. Many (large) organizations have a system of discipline in place, which can range from administering a warning to a summary dismissal (Meerts 2018a). In this way, the problem for the organization may be solved in an efficient way, allowing the organization to act swiftly and move on.

Conclusion

Employee theft of employer property, defined as "stealing, use, or misuse of an employer's property or assets by an employee without permission," is a serious problem for organizations. Theft can take many shapes and sizes and may be committed by a variation of employees in different positions within an organization. While it is known that many organizations make an effort to prevent employee theft through prevention measures and private security solutions (such as the use of ▶ "Security Guards: Authority and Power", ▶ "Physical Security: Video Surveillance, Equipment, and Training", and ▶ "Cybersecurity: Preparedness"), it is often assumed that when a crime does occur, the investigations of it will be handled by the criminal justice system. However, much of the investigations into and solutions sought for employee crime remain entirely in the private sphere. This leads to a situation in which it is very difficult to provide a meaningful estimation of the scope of the problem of employee crime.

Definition

Pollution is the introduction of human-made, physical, and chemical substances into the environment that cause harm to people and other living organisms. Commonly, pollution results from people interacting with the environment, and those human activities pollute the environment, adversely affecting drinking water, soil, and air. Investigation of environmental pollution dumping is a fact-gathering process to determine whether pollution was intentionally dumped with indifference to the law and/or the harm that pollution actually or potentially causes.

Introduction

This entry describes the areas and factors by which investigations determine how environmental pollution became concentrated, known as *pollution dumping*. *Anthropogenic* pollution is environmental pollution caused in nature by humans or human influence, and it affects every living organism. Since 1950, 140,000 new pesticides and chemicals have been created by manufacturing companies, some of which are toxic, such as hydrochlorofluorocarbons (HCFCs), polychlorinated biphenyls (PCBs), and dichlorodiphenyltrichloroethane (DDT). Unfortunately, many of these chemical pollutants are being dumped into the environment, causing areas to become oversaturated (Arora et al. 2018). Investigative processes address pollution dumping for each of the following seven types of environmental pollution – air, water, radioactive, soil, noise, light, and thermal.

Environmental Pollution

There are seven recognized forms or *types* of pollution: air, water, radioactive, soil, noise, light, and thermal. Pollution dumping resulting these pollution types can be waste in the form of solid, liquid, gas, or energy. Solid waste is merely solid material discarded as useless, such as non-recyclable and non-biodegradable materials. Liquid pollutants include industrial wastewaters and human sewage. Greenhouse gasses are comprised of methane, carbon dioxide, and nitrogen oxides. Noise pollution is energy in the form of sound pressure levels that disturb daytime communication and nighttime rest. Light pollution is the obstructive illumination of nature, including hindering the night sky view. Thermal pollution equates with global warming, resulting in an increasing temperature in nature.

The investigation focus of environmental pollution dumping is referred to as the *source*. Generally, pollution is caused by human activity and can be categorized as either a *point source* or *nonpoint source*. The point source is the origin of a specific pollution dump that can be located. Alternatively, a nonpoint source has no boundary. Known as *diffuse pollution*, its origin is difficult to pinpoint. Unclean river water is considered diffuse pollution if the pollution dumping source cannot be identified. Investigations have determined that sources of river water pollution can

be domestic, such as bathrooms and kitchens, or that the pollution dumping is from industry, agriculture, and/or transportation (Munafo 2005).

Associated with each source of pollution is its *pathway*, or *route of entry*, to the recipient. The pathway identifies how the pollutant travels from the source into the environment and then how it contacts the human body or another recipient. The *effects* of toxic pollution dumps dissipate with *dispersion*, *dilution*, *deposition*, and/or *degradation*. Investigations into active pollution dumping incidents seek to confirm that the impact is mitigated as (a) smoke disperses into the air and away from the source, (b) liquid and soluble pollutants are diluted, (c) suspended solids are deposited on river beds, or (d) the composition of the pollutant breaks down (Woodrow et al. 2018).

Finally, our natural resources of water, air, soil, and land are negatively impacted by pollution. Depending on the type of pollution, these sectors are affected in different ways. Investigations have shown that deliberate pollution dumping sites are locally unwanted land uses (LULUs). In the United States, when population centers are near LULUs, they are usually low income and often non-white communities. Ecological awareness in the general population is high in negatively impacted regions, but environmental concerns in society-at-large for those living in environmentally at-risk areas are minimal (Bullard 2000). *Not in my backyard* (NIMBY) has emerged as an effective response strategy against localities and companies who try to engage in pollution dumping in rural, destitute areas. Environmental pollution dumping investigations are often associated with NIMBY campaigns (Bullard 2000). In the rest of this entry, the seven types of pollution are described along with how they are investigated in terms of source, pathway, and consequences.

Air Pollution

Air pollution is the contamination of natural air with harmful vapors, fumes, and chemicals. Causes of this pollution dumping into the atmosphere include vehicle gas emissions, burning materials, and harmful industrial by-product fumes (Arora et al. 2018).

Globally, air pollution contributes to atmospheric changes but has a *nonpoint source* that is difficult to isolate worldwide. Locally, however, air pollution dumping often has a *point source* that is known by nearby resident populations. Common local sources of air pollution dumping include wood and charcoal burning by households, small businesses, manufacturing, and vehicles. Air pollution is not always visible or odorous. Deadly carbon monoxide and dangerous carbon dioxide, usually nonpoint sources, are invisible and odorless gasses.

Local investigations manage these environmental situations since the polluting businesses impact all households in the region, regardless of culture or development level. An investigation into tropical streams showed that warmer temperatures have affected macroalgae, which in turn have caused changes in the fish physiology and diversity (Rolla et al. 2009). Investigations have also shown that a consequence of dumping harmful chemicals into the atmosphere as pollutants, such as carbon dioxide, pollution, increases climate change (Zinabu and Pearce 2003).

When the concentration and toxicity of air pollutants are high, the effects are worse for the environment, making it difficult to eradicate particularly following seasonal or natural changes. Higher concentrations of air pollution dumping result in breathing issues for anything alive. Additional effects of air pollution include increases in smog prevalence, acid rain, higher asthma incidences, and crop depletion from less oxygen. Then, as a result of environmental risk factors due primarily to air pollution, health-care costs increase at an alarming rate (Arora et al. 2018).

Water Pollution

Water pollution is contamination by pollutants that decrease water purity, characterized by excess chemical or biological substances causing harm to living organisms. Biological water pollutants are microorganisms responsible for waterborne diseases and thus are harmful to all life forms. If not contained and treated, feces from infected organisms allow pollutants to seep into the surface and groundwater. Sometimes a *nonpoint source* of water pollution occurs as illegal dumping in

rivers, lakes, oceans, and underground reservoirs. This water pollution dumping then affects these water sources, as well as soil moisture and groundwater in aquifers. Next, the now-polluted rivers flow into the ocean and damage the marine environment. Dispersion in large bodies of water dilutes the pollutant, so the most significant harm is at the river mouth. Symbolized by large oil spills and groundwater oil seepage, water pollution is one of the most dangerous types of pollution because it decreases the available drinkable water and irrigation supply (Arora et al. 2018).

Industry environmental regulations, promulgated by Congress and enforced by the US Environmental Protection Agency (EPA), are established to protect the water supply from toxic chemical pollution dumping. Investigations and research have shown that rigorous environmental regulation does not damage industrial competitiveness. In investigating corporate compliance with the rules, Michael Porter saw that innovation and technology led to "improved competitiveness" (p. 115) in avoiding pollution dumping. Over the years as a result of local environmental pressure, Dow Chemical closed wastewater evaporation ponds and redesigned its processes, costing the company $250,000 but saved $2.4 million per year in reducing toxic pollution dumping by 6,000 tons annually (Porter and van der Linde 1995).

Oversight and investigations of industrial by-product dumping in groundwater, streams, lakes, and oceans remain an ongoing effort, as other water pollution dumping approach their limits. USA Today reported that a 600,000 square mile patch of plastic trash twice the size of Texas is floating in the Pacific Ocean. The mass dumping of plastic with its subsequent coagulation and environmental pollution is destructive, beginning with marine life but eventually trickle back to human (Eriksen et al. 2014). Water pollution dumping investigations and research are being done because additional data regarding the consequences is needed.

Chemical pollutants also include heavy metals, pesticides, and other persistent pollutants. Heavy metals are a group of toxic chemical pollutants that contain compounds of persistent metals such as mercury, cadmium, lead, and chromium. The concentration of heavy metals in water in excess of acceptable levels can cause illness and death among animals and humans, if consumed through drinking and food (Zinabu and Pearce 2003). According to Förstner and Wittmann (2012), the first trace metal aquatic pollution investigations on lakes were done in 1973 in Germany. Practices determining the concentration of heavy metals concluded the level of arsenic decreased with water depth, but the concentration of chromium increased. Investigations found the metal concentration increase in living water organisms was relative to time, seasonal variations, and the initial level of metal distribution in the organism. Marine life near the surface, closer to other pollution-dumping sectors, was more contaminated (Förstner and Wittmann 2012).

Radioactive Pollution

One of the most dangerous types, radioactive pollution is defined as the increase in natural radiation levels caused by human activities. Handling and processing of radioactive materials and storing radioactive waste are extremely dangerous, causing congenital disabilities, cancer, and health deterioration (UNEP n.d.). A *point source* that diffuses more slowly than other types of pollution dumping, radioactive pollution causes include nuclear power plant accidents, incorrect nuclear waste disposal, and nuclear storage leaks. Investigations improved safety and disposal procedures, and the nuclear fallout resulting from explosive testing has decreased since the 1970s, but environmental radioactive pollution dumping is still negatively impacting marine organisms (Kennish 2017). An investigation into a Mayapuri, India, radiation incident revealed the source as contaminated scrap metal from a Delhi University chemistry lab irradiator had been sold, dismantled, and distributed. Eight people were hospitalized as a result of the radiation exposure; one of them died (Yardley 2010).

Soil Pollution

Soil pollution, known as land pollution, contaminates and then hinders plant and animal biological life. Linked to water pollution, soil pollution

causes include non-sustainable farming practices, hazardous waste, and its seepage into the soil, mining, and littering. In addition to poisoning of nearby land and water, soil pollution causes reduced agriculture yields. Soil pollution is a point source, depleting the land of nonrenewable resources, diminishing biodiversity, and gathering harmful, unmanageable chemicals. Investigations discovered that liquid wastes from latrines or industrial waste storage containers flow with pathogenic microorganisms and toxic chemicals onto the land surface and slowly seep into the soil, permeating and contaminating groundwater. Leachate is the result, which percolates into the soil with its toxic, polluting chemicals (Arora et al. 2018). The United Nations manages and mitigates environmental pollution collaborative processes. According to the UN Atlas of the Oceans (2016), degradation of oceans and seas nearshore has polluted land, reducing crop yields and resulting in ecological damage. The negative changes involve atmospheric and sediment flow changes and habitat loss. Mitigation resulting from investigations included cleanup responses and management closure or restriction reprimands (UN Atlas of the Oceans 2016). Ecological strategies for a framework to investigate pollution were proposed in 1980s, beginning with comparing, contrasting, and evaluating pollution detection processes. Interpreting pollution, such as identification and species impact, was the next step, followed by prediction (Underwood and Peterson 1988). MIT led a recent multicity investigation into land-based urban stormwater management, as opposed to underground pipes that have leached pollution into the soil. The investigation found that land-based runoff is sustainable, decentralized, and more easily manageable by institutional mindsets with sustainable objectives (Schulman 2018).

Noise Pollution

Noise pollution is created by human activity disrupting the lifestyle or ability to work in an affected area. Noise pollution dumping can originate with loud music events, airplanes, traffic, railroads, or fireworks. Temporary or permanent loss of hearing can harm wildlife. Noise pollution is generally a point source unless an entire community or region is inundated with the same disruptive sound source (Stansfeld and Matheson 2003). The LIFE MONZA project aim was to establish a methodology to investigate the annoyance factor relative to noise pollution – Methodologies for Noise Low Emission Zones. But the process and results were not authoritative since annoyance is a feeling and its subjective nature cannot be captured in a questionnaire (Arcangeli et al. 2018).

Light Pollution

Light pollution is an obstructive, illuminating point source that prevents the natural from occurring, such as insects navigating correctly and the prey defenses of bats (Gaston et al. 2013). Investigative research has shown that light pollution dumping occurs in large, modern urban centers. Light pollution interferes with nesting sea turtles along a beach highway as well as hindering specific investigative tasks, such as astronomical observation. If the stars cannot be seen, the area is polluted with light (Longcore and Rich 2004). Light pollution dumping is obstructing man's attempt to study nature, a spectral investigation sought to measure the impact of "sky glow" in reducing the ability to see more of the night sky. Results showed that the amplified visual glow from LED lighting has increased the dimmed, *scotopic* sky brightness to where 70% of Americans and more than 50% of Europeans cannot see the Milky Way (Luginbuhl et al. 2013).

Thermal Pollution

Thermal pollution, a nonpoint source, is an increase in temperature in nature occurring over a specific period of time. The heat is often due to carbon gasses trapped from air pollution. Deforestation, a high regional carbon footprint, and power plants can cause temperatures to rise. Slight fluctuations are normal, and life can adapt, but quick changes in nature's temperature cause the water supply to diminish and a loss of wildlife. Global warming has resulted in warmer oceans and oceanic thermal expansion, thus reducing land availability (Arora et al. 2018). Studies, rather than investigations, are ongoing, measuring

the impact of thermal pollution on the environment. Global warming is responsible for decreasing the permafrost region by up to 35%, releasing pathogenic bacteria and viruses that have been buried until now (Wright 2017).

Conclusion

Human action initiates pollution, the result of which can cause additional pollution. All pollution is interconnected, so sustainable strategies are needed that address affected environment sectors at the source. For example, *municipal solid waste* (MSW) impacts all sectors – water, soil, and air. MSW is the accumulation of everyday items that are discarded by the public as trash. Systems addressing MSW in large, industrialized Asian cities combine four methods to achieve optimal management results: analysis, data acquisition, mathematical projection, and identification. With identifiable domestic and industrial point sources, the pollution effects dissipate when separated from large urban centers because the pathway to recipients is controlled. A study of Bangalore, India, results, with both door-to-door and *community bins* (CB) collection, revealed that overall expenses decreased with an increased CB pickup rate (Mondal et al. 2018). This investigation outcome is key because it underscores the importance of municipalities proactively addressing a pollution dumping challenge.

Pollution exacts a heavy toll on nature and life in general but especially upon the immediate population. "Personal efficacy," according to Bullard (2000), is the needed response adopted in recent years to cope with *environmental stressors*. Stressors include municipal solid waste facilities, industrial plants with chemical emissions, toxic waste dumps, and hazardous waste landfills. Disproportionately, as mentioned previously, those most directly impacted by pollution dumping tend to be low income and a different race or culture. The decision to speak out against what is happening to those affected in their backyard is a difficult one. Investigations with the social justice movement have raised awareness and are well documented. More investigations and research to support the body of evidence, however, are needed for the environmental advocacy movement. *Problem-focused coping* is the approach that directly addresses the pollution dumping issue with facts, receives media coverage, and is subject to peer review in the community. Not only in poor, rural areas but everywhere, people are taking note of what is happening in their backyard and taking action (Bullard 2000).

In addition to local investigations and activism oversight pertaining to environmental pollution dumping, compliance enforcement provides the regulatory control. Furthermore, Keith Hawkins proposed decades ago, after a 30-month study, that the social definition of pollution provides a strong "accusatory and adversarial" deterrent to being a polluter. He called this a *sanctioning strategy*. Private companies, as well as public and government entities, understand the importance of inhibiting pollution dumping to avoid public scrutiny (Hawkins 1984). Going forward, contemporary investigations will be central in recognizing successful efforts to mitigate and reduce the impacts of environmental pollution dumping.

Firearm · Gun · Ammunition · Gunshot residue · Chemistry · Ballistics · Shooting reconstruction · Forensic · Investigation

Definition

Breech the rear end of the barrel where the cartridge is inserted

Class characteristics identifying features of an object based on comparison to known standards or an established set of criteria

Individual characteristics features of an object that distinguish it from objects in the same class

Muzzle the front end of the barrel from which the projectile emerges

Introduction

Investigations related to firearms include forensic firearms examinations, gunshot residue analysis, wound examinations, and shooting reconstructions. Forensic firearms examinations encompass the analysis of the firearm and ammunition, such as firearms operability testing, microscopical bullet and cartridge case comparisons, and serial number restorations. Gunshot residue examinations consist of the chemical, microscopical, and spectroscopic examinations of residues that result from discharge of the ammunition within the firearm, specifically the primer and gunpowder. Gunshot residue examinations are often conducted to determine a muzzle-to-target distance or estimate a maximum distance at which a firearm will cease to deposit residues on a target. Examination of gunshot wounds can further assist in investigations, providing information about the nature of injuries sustained by a surviving shooting victim or the cause and manner of death of a decedent. The latter determinations are done during an autopsy and may include mapping the wounds and determining the trajectory of the projectile(s) within the body during external and internal examinations, respectively. The culmination of data obtained through the examinations of the firearms and ammunition, gunshot residue analysis, and wound patterns combined with trajectory analysis (often broadly referred to as "ballistics") at the crime scene aid in the overall goal of developing a shooting reconstruction. These shooting reconstructions further incorporate information obtained during the course of the broader investigation and may include blood pattern analysis, recognition and examination of physical traces, recovery of digital traces, witness statements, and any matters related to standard forensic and police investigation methods.

Ballistics is the study of a projectile's movement from the trigger pull through to the projectile's interaction with the target. Internal ballistics occurs within the firearm when the firing pin strikes the cartridge and all subsequent events until the projectile exits the muzzle end of the barrel. External ballistics is concerned with the actions of the projectile from the moment it exits the firearm and travels a path for some distance until the projectile reaches the target. This involves any potential interactions of the projectile with intermediary objects or surfaces. These interactions may result in changes in the speed, direction, or overall behavior of the projectile. Terminal ballistics includes the interaction of the projectile with the target. Trajectory analysis takes into consideration all three types of ballistics with the goal of developing a shooting reconstruction.

Most importantly, each individual phase of firearms investigations (from the initial examination of the scene to the laboratory analysis) and the overall interpretation of resultant facts to develop a reconstruction of events are scientific endeavors (De Forest 2005). The fundamental basis for such forensic investigations is that activities such as shootings will generate traces which can be recognized, collected, and analyzed by qualified scientists with the ultimate goal of applying logical

reasoning and critical thinking to the consideration of alternate hypotheses, contextualizing events, and providing a meaningful interpretation of events to aid in fact-finding endeavors. Firearms investigations, in part or as a whole, are subjected to evidence admissibility requirements (e.g., the Frye, the "Daubert trilogy" or the Federal Rules of Evidence guidelines in the United States of America) and therefore should be conducted with scientific rigor, transparency, and neutrality.

Firearms and Ammunition

The legal definition of a firearm may vary from one jurisdiction to another. According to 18 U.S. Code § 921 (3), "the term firearm means (A) any weapon (including a starter gun) which will or is designed to or may readily be converted to expel a projectile by the action of an explosive; (B) the frame or receiver of any such weapon; (C) any firearm muffler or silencer; or (D) any destructive device. . ." [Supplemental definitions are provided for a destructive device (18 U.S. Code § 921 (4)) and a firearm muffler/silencer (18 U.S. Code § 921 (24))]. Firearms can be classified as handguns or long guns. Handguns can be further subdivided into revolvers and pistols, and long guns can be subdivided into rifles, shotguns, submachine guns, and machine guns. Firearms that are homemade are generally referred to zip guns, and firearms may be modified, such as a sawed-off shotgun or through the addition of a muzzle/flash suppressor. Handguns, rifles, submachine guns, and machine guns have a rifled barrel consisting of a series of lands and grooves along the length of the barrel produced during manufacture. The method of producing the rifling can vary, with some methods imparting characteristic tool marks along the barrel (Rowe 1988). This rifling imparts a spin to the bullet, and it is these marks that can be transferred to the bullet as it travels down the barrel when a firearm is discharged.

The primary components of ammunition are the case, the primer, the propellant, and the projectile (bullet), which can be collectively referred to as the cartridge. One purpose of the cartridge is to expand and seal the rear of the firearm during firing in order to prevent the escape of gases and overall loss of pressure from the breech end of the barrel. As pressure increases within the cartridge, the bullet is forcibly released from the cartridge and the projectile is propelled down the barrel, exiting at the muzzle end of the firearm. Each component of the cartridge can vary in physical or chemical properties.

The case can differ in physical characteristics, such as shape and primer location, features which are used to classify the ammunition. For example, cartridge cases can be described as straight, bottlenecked, or tapered and can be further described as rimmed, semi-rimmed, rimless, rebated, or belted. In general, cartridge cases are brass (an alloy of copper and zinc). The location of the primer within the cartridge can vary, with rimfire and centerfire being the most common types of cartridges. Rimfire cartridges contain the primer spun into a circular rim at the edge of the case, and centerfire cartridges have a primer cup inside the center of the cartridge case. The primer cup holds the priming mixture within the base of the cartridge case. Centerfire cartridges can be further subdivided into Boxer or Berdan priming systems, depending on the location of the anvil, which is the metal component associated with the primer cup (Heard 2013). Upon trigger pull, the firing pin of the firearm will strike the primer cup and the priming mixture will be crushed against the anvil, whether it is contained within the primer cup (Boxer) or incorporated into the case (Berdan). This friction will result in an explosion within the cartridge, which will ignite the propellant (gunpowder). The propellant will burn at a controlled rate, which depends on its quantity, shape, size, and chemical composition.

The projectile, or bullet, is defined by its caliber, which corresponds to the diameter of the bullet. Bullets can vary in shape (e.g., round nosed, elongated, or hollow point) and the presence, absence, and type of jacketing (e.g., non-jacketed, semijacketed, full-metal jacket). The core of the bullet is often lead and the jacketing bronze (copper–tin alloy). Projectiles may also be polymer coated, frangible, or "green" (nontoxic) depending on the intended purpose of the

ammunition, each of which will result in variation to the chemistry and physical characteristics of the projectile and overall ammunition composition. In addition, bullets may contain cannelures, grooves around the bullet that hold lubricant and seat the bullet within the cartridge case.

Shotgun ammunition (shells) contains the head (brass), the primer, a tube (which can be plastic or paper), gunpowder, the wad, the projectile(s), and may contain buffering material. The wad seals and separates components of the ammunition, and can vary in its composition, which may be paper, plastic, or cardboard. The projectile can be either a single rifled slug or spherical pellets of varying size and weight (referred to as the shot, which can be further classified as birdshot or buckshot depending on the diameter of the pellets). The buffering material is a polymer that may be added to the shot in an effort to minimize pellet deformation. In shooting cases involving shotguns, components of the ammunition may be found at the scene, adhering to a target surface, or within the shooting victim.

Forensic Firearms Examinations

Forensic firearms examinations encompass the analysis of the firearm and ammunition, such as firearms operability testing, microscopical bullet and cartridge case comparisons, and serial number restorations. Examinations in the forensic firearms laboratory include physical examination and classification of the firearm, and additional analysis may include function (dry fire) testing; trigger pull testing; evaluation of malfunctioning, damaged, modified, homemade, or antique firearms; and shooting-related tests such as muzzle-to-target determinations, cartridge case ejection pattern determinations, body armor tests, and test bullet recovery. In addition, firearms examinations may include the utilization of databases for bullet and cartridge case comparisons and gun linkages, such as the Integrated Ballistics Identification System (IBIS).

Prior to forensic firearms examinations, the examiner should consider the presence and recovery of traces from the firearm and any associated ammunition. These traces can include fingerprints, blood spatter, tissue or bone fragments (which may be present on the exterior of the firearm or within the barrel), and any other microscopical traces that may be adhering thereon (such as hairs, fibers, glass, etc.). The firearm should be examined visually and stereomicroscopically in an effort to record its gross physical features. The examiner may note characteristics such as color, make, model, manufacturing markings (such as serial numbers, proof marks, part numbers, and country of origin), caliber (the measurement from land to land for a rifled barrel) or gauge, type of firearm (action; single or double), ammunition type and capacity (which includes the examination of the magazine, if present), size (length of barrel and overall length of the firearm), rifling characteristics (e.g., polygonal), and the presence, absence or modification of safety features. Examiners should look for and document faulty components, damage, alterations, or wear to the firearm.

Microscopical analysis of ammunition may be based on bullet comparisons or cartridge case comparisons, depending on the items recovered during the investigation and submitted to the laboratory for analysis. These examinations are conducted with a comparison microscope, that is, two microscopes attached by a bridge that allows for simultaneous viewing of both objects when viewed through the oculars. Comparisons can be between projectiles or cases recovered from the scene (unknowns), between test fires (knowns), or between knowns and unknowns in an effort to establish common origin (to link a projectile or a cartridge to a particular firearm). This is based on the premises that (1) the firearm may impart characteristics from the barrel onto the bullet as the bullet travels down the barrel after discharge and prior to exiting the firearm and (2) the firearm may impart characteristics from the breech face and/or firing pin onto the cartridge case upon depression of the trigger and the force of the discharge process.

Examinations are conducted on both intact bullets (that may or may not be damaged or distorted) and fragments of the bullet core or jacket. With bullets, the examiner will evaluate

class and individual characteristics, and note features such as caliber and general rifling characteristics. Specifically, the examiner may note the degree and direction (left or right) of twist, number and width of the lands and grooves, and the depth of the grooves on the bullet as well as any additional markings or imperfections that may be traced to a particular firearm. For cartridge cases, the examiner will evaluate headstamp information located on the base of the cartridge case to determine caliber and manufacturer and will look for the presence of marks that would result from cycling, chambering, extraction (extractor marks), ejection (ejector marks), and impacts with the breechface and the firing pin. The breechface and firing pin impressions will be examined in detail in an effort to locate class and individual characteristics that can be compared between cartridge cases. Prior to the preparation of the projectile for comparison microscopy, the bullet should also be examined for the presence and recovery of any adhering traces. The analysis of biological traces utilizing serological and DNA methods may provide investigatory information about the trajectory of the projectile including its interaction with an individual. The detection and examination of nonbiological traces may further provide information about the path of the bullet and its interaction with intervening targets, such as clothing (fibers or a fabric impression), a wall or door (paint, plaster, sheet rock, wood), a vehicle (glass, paint, metal), or the ground (plant matter, soil, asphalt). It should be kept in mind that anything can be an intervening object, and based on Locard's exchange principle, the object and the projectile can transfer material from one to the other (Petraco and De Forest 1990).

Serial number restoration may be conducted in a forensic firearms laboratory in an effort to restore defaced firearms. Firearms may be defaced using a variety of methods, such as gouging, grinding, or over stamping. Various regents, including acid solutions, may be utilized for chemical restoration along with abrasive cloths of varying coarseness for polishing of the defaced area. Prior to application of restoration methods, the examiner should visually inspect the defaced area in an effort to determine the possible method of obliteration and to remove any potential traces that were deposited during the defacement. Determining the method of obliteration may aid in determining the best methods for successful restoration. The serial number can be used to track the provenance of the firearm, from manufacturer to ownership.

Gunshot Residue Analysis

Gunshot residue examinations consist of the chemical, microscopical, and spectroscopic examinations of residues that result from discharge of the ammunition, specifically the primer and gunpowder. Gunshot residue examinations are often conducted to determine whether or not someone may have discharged or handled a recently discharged weapon, a muzzle-to-target distance, or a maximum distance of deposition. In addition, gunshot residue analysis methods may be employed to determine if a projectile came into contact with a surface. Such examinations will look for chemical components consistent with bullet "wipe" or "splash," which can include residue from the bullet (copper, lead), lubricant from the ammunition, and residue from the barrel that is transferred to the bullet in addition to adhering residues from the primer and propellant.

Gunshot residues are often divided into inorganic and organic residues, with the organic residues being a combination of products from the individual components of ammunition ejected from the muzzle end of the firearm upon discharge (directed toward the target) and inorganic residues being largely derived from the primer and exiting toward the rear and sides of the firearm (generally directed toward the shooter). These latter primer residues are often analyzed in "shooter's hands" cases to determine if an individual recently fired, handled, or was in the vicinity of a discharged firearm. Despite the name, collection of samples is not restricted to the shooter's hands, and may include the face, hair, and clothing of the suspected shooter as well as objects in the vicinity of the shooting. The elemental composition of these samples has historically been analyzed

using atomic absorption spectroscopy (AAS) and scanning electron microscopy-energy dispersive x-ray spectrometry (SEM/EDX). The SEM/EDX is more commonly utilized because in addition to elemental data, the instrumentation also provides critical morphological characteristics of the primer residues, which is important during the interpretation phase of analysis (Zeichner 2009).

The basis for inorganic gunshot residue testing is the chemistry of the primer. The primer is composed of a combination of an initiating explosive, an oxidizing agent, a fuel, sensitizers, frictionators, and binding agents. Compositions may vary and also include dyes or proprietary components. SEM/EDS analysis is based on detecting the most commonly encountered elemental profile in standard ammunition, specifically lead, barium, and antimony resulting from lead styphnate (initiating explosive), barium nitrate (oxidizing agent), and antimony sulfide (fuel), respectively. A characteristic primer residue particle consists of barium, antimony, and lead and has spherical morphology. Additional guidelines and standards have been established for classifying and interpreting resultant elemental and morphological data in primer residue cases (see, for example, ASTM E1588-17 2017).

Gunshot residue analysis can also be conducted in an effort to determine a muzzle-to-target distance or estimate a maximum distance at which a firearm will cease to deposit residues on a target. The premise is that the size of the residue pattern is a function of distance and both the firearm and ammunition employed; as the distance between the muzzle and target decreases, the size (diameter) of the pattern will decrease and the concentration of residues deposited on the target will increase. The generation of these residues is largely based on the chemical composition of the propellant, although residues that exit the muzzle end of the firearm could also come from the primer or the bullet as well as from the firearm itself, which may contain lubricants, residue from cleaning products, and general build-up of soot and materials within the barrel ("fouling"). Traditional black powder (a mixture of potassium nitrate, charcoal, and sulfur) ammunition has been replaced by black powder substitutes and the more common smokeless powder, and ammunition can vary in smokeless powder composition – single based (nitrocellulose), double based (nitrocellulose, nitroglycerine), and triple based (nitrocellulose, nitroglycerine, nitroguanidine). Smokeless powder may also consist of various additives, such as coatings, stabilizers, plasticizers, lubricants, and dyes, some of which may be proprietary and unique to a manufacturer. Smokeless powder can be further characterized by its morphology and size, making microscopical examination of powder particles to determine physical characteristics an important aspect of gunshot residue examinations. The most common colorimetric methods for resolving gunshot residues on targets (often conducted on victim's clothing) are dithiooxamide/rubeanic acid for the detection of copper, sodium rhodizonate for the detection of lead, and the modified Griess test for the detection of nitrites. Additional analytical methods have been employed to detect and identify gunshot residues, including Fourier transform infrared spectrometry (FT-IR), x-ray fluorescence (XRF), gas chromatography (GC), liquid chromatography (LC), and capillary electrophoresis (CE) (see Dalby et al. 2010 for a review of literature pertaining to gunshot residue analytical methods).

Several factors can influence the deposition and retention of gunshot residues (Nichols 2004). Interpretation of gunshot residue patterns requires consideration of intervening targets, the handling of objects containing the residues, and modifications to the firearm, such as the addition of a muzzle/flash suppressor. The detection of gunshot residues and distance determinations can also be conducted with shotgun pellet patterns, making gunshot residue examinations useful for both handguns and long guns. The size of the shotgun pattern is primarily controlled by the distance (range) and choke (muzzle diameter) of the gun while the number of pellets is controlled by the gauge and load of the shell used.

Shooting Reconstructions

The culmination of data obtained through the battery of tests conducted during forensic firearms examinations, gunshot residue analysis, wound

interpretations obtained from the shooting victim (s), and trajectory analysis at the crime scene contribute to the overall goal of developing a shooting reconstruction. Shooting reconstruction at the scene includes documenting bullet holes, utilizing trajectory rods or lasers to trace the pathway of the bullet, and examining physical traces such as bloodstains and digital traces such as CCTV footage. Additional scene work may also include determining the sequence of shots within a target (e.g., a series of shots in a vehicle windshield) and shot accounting, or "reconciling the number of fired cartridge cases, fired bullets, bullet holes (in inanimate objects), and bullet wounds" (Hueske 2006, p. 248). Additional information can be ascertained from the detection of gunshot sounds based on witness statements or gunfire detection technologies (Haag and Haag 2011). Information derived during detection and investigation, such as witness statements and reviews of phone records, are also incorporated into the reconstruction effort with the goal of developing a timeline of events.

External and internal examinations of the shooting victim can aid in determining entry and exit wounds as well as the pathway of the projectile(s) within the body (DiMaio 2016). Examinations of the body can be aided by obtaining x-rays to locate projectiles, whether intact or fragments. These projectiles can subsequently be recovered and submitted to the forensic firearms laboratory for microscopical examination and comparison. From such data and the examination of physical traces at the scene, it may be possible to determine position and location of the shooting victim(s) at the time of the incident. Trajectory analysis involves understanding the nature of the projectile in flight. The bullet travels a curved path and is subjected to external forces such as air and gravity (Rinker 2007). Interior forces of pressure and energy, which are functions of the individual ammunition components as well as the firearm, will also impact the trajectory of the projectile. As the bullet interacts with different surfaces, the trajectory, speed, and behavior of the bullet may change. One aspect of trajectory analysis is ricochet analysis, which deals with the rebounding of the bullet off of a hard surface that may result in an angular (directional) change in the bullet's trajectory. By examining the location of a projectile recovered at the scene or in a victim and evaluating the trajectory of the projectile(s) including any factors that may contribute to changes in the path of the bullet (such as the aforementioned intervening targets and ricochets), it may be possible to determine the approximate location of the shooter during the incident. Such information can be further supported by considering cartridge ejection patterns and the location and distribution of gunshot residues.

Conclusion

Firearms investigations are multifaceted and complex. Whether investigating an apparent suicide, a police-involved shooting, or a mass shooting, there are many layers to the process of developing a shooting reconstruction to determine a sequence of events. During the initial crime scene investigation, evaluation and preliminary interpretation of the scene as traces are being collected for further laboratory analysis is imperative to develop and refine hypotheses and consider alternate hypotheses for evaluation. The importance of educated, well-trained scientists at such complex scenes is critical and essential. Shooting reconstructions require consideration of myriad examinations including identification and testing of the firearm(s) involved, microscopical analysis and comparisons of ammunition, gunshot residue analysis, victim wound analysis and interpretation, and overall trajectory analysis. Reconstructions should set out to determine the locations and movements of the shooters and the victims, the weapons used in the shooting, and any additional information that may accurately recount the shooting event. By utilizing data from the examinations, it may be possible to reconstruct the events so as to support or refute the accounts of witnesses or suspects.

Definition

A fraud investigation is a thorough and objective, fact-gathering process conducted to determine whether or not a fraud-related crime was committed. Evidence is collected during this process to establish facts, inform findings, protect victims, and build a case which may potentially culminate in a criminal and/or civil action.

Introduction

Fraud investigations are a specific type of investigation conducted to determine whether a fraud-related crime was committed. Public attention to the phenomenon fraud investigations increased following a series of public company frauds in the early 2000s (Coenen 2009, xv). Many of those crimes are listed among the "Ten Biggest Frauds in Recent U.S. History" and include Enron in 2001, Tyco International and WorldCom in 2002, and HealthSouth in 2003 (Forbes 2017).

There are many different types of frauds in existence. Overall, there are types of frauds that can be perpetrated across several industries, such as check fraud, and frauds that can be specific to an industry, such as healthcare fraud. Here, the focus is on occupational fraud. Occupational frauds are those committed by an employee, to the detriment of the organization (ACFE). In that realm, the primary types of occupational fraud are corruption, asset misappropriation, and fraudulent statements (ACFE).

Fraud investigations should commence with careful background research and the creation of an investigative plan. Careful planning is critical to the success of a fraud investigation. Once the investigation commences, investigators will determine the best approach, based on information gleaned during the planning phase. Next, evidence is collected, with a keen eye toward "following the money." Intelligence is gathered to gain additional insight, with an eye toward potential litigation. The ultimate goal is a detailed case file, documenting all information gathered.

While many similarities in investigative practices exist across all investigations, fraud

investigations have specific challenges. One is a time crunch. There is a certain haste to solve a fraud-related crime, in order to prevent further victimization. Another is the complexity associated with fraud matters. Fraud schemes can be complicated, and the documentation involved can be voluminous. Thus a fraud investigation might require the assistance of one or more experts. For this and other reasons, one seasoned investigator said he would rather work on a homicide case than a fraud investigation (Giacalone 2015). Yet with the proper planning, investigating a fraud case can be a rationalized and rewarding experience.

Fraud Investigation Resources

One leading authority on conducting fraud investigations is the Association of Certified Fraud Examiners (ACFE). The ACFE, founded in 1988, is the world's largest anti-fraud organization and provider of anti-fraud training and education. As of this writing, they have over 80,000 members, globally. Their mission is to reduce the incidence of fraud and white-collar crime and to assist the Membership in fraud detection and deterrence (ACFE 2018). The ACFE categorizes a fraud investigation as one of the four basic components of a general fraud examination. The other three components of a fraud examination are financial transactions and fraud schemes, law, and fraud prevention and deterrence (ACFE 2014). They also provide a detailed guide for fraud examiners called the "Fraud Examiners Manual" to assist investigators in conducting their investigations.

Fraud Investigation Practices

Planning Phase

To begin, the investigator should meticulously plan his/her case. Fraud investigations should be approached as any other investigation would – as "an impartial, non-judgmental, fact-gathering process" (Biegelman and Biegelman 2010, p. 296). The early steps are critical to the success of a fraud investigation (Biegelman and Biegelman 2010, p. 296). Investigators should conduct an initial review of the available documents to determine the fraud allegations. A more detailed review will occur later, as the investigation progresses.

Today, the types of documentation available to investigators is vast. In the corporate setting, "documentation" may include but is not limited to "contracts, invoices, correspondence, memoranda, weekly reports, presentations, telephone messages, emails, reports, performance reviews, performance improvement plans, medical records, and other written or recorded material" (ACFE 2014, p. 3.118). Investigators may also want to obtain credit statements, bank accounts, and social media posts (Giacalone 2015). It is important for investigators to ensure that all data, especially electronically obtained data, is saved, secured, and documented in the case file (Giacalone 2015).

From the documents, the investigator should gain a thorough background of the allegations. A keen understanding of the allegations will be important in the development of the investigative plan. From the documents reviewed, investigators will learn the resources required to conduct the investigation (Biegelman and Biegelman 2010, p. 296).

At this time, the investigator should determine the type of fraud that may have occurred. This information will help the investigator to develop the appropriate team to assist in the investigation. Depending on the allegations, fraud investigators may require the expertise of auditors, attorneys, fraud examiners, managers, and security personnel, among others (ACFE 2014, p. 3.128). The investigative team will also include partners in federal, state, and/or local agencies, depending on the type of fraud-related crime uncovered (Giacalone 2015).

Investigative Plan

Before commencing a fraud investigation, the investigator should develop an investigative plan. Generally speaking, most investigative plans will include a framework for the use of financial, personnel, and technological resources.

Each member of the investigative team should be invited to contribute to the plan. Their active participation in the plan will be prosperous for the overall investigation (ACFE 2014, p. 3.135). In the corporate setting, an investigative plan will need to be cleared/approved by in-house counsel and/or retained outside counsel (Biegelman and Biegelman 2010, p. 296).

The investigative plan can help with the investigation by ensuring an established strategy is in place, with adequate resources to accomplish the investigative tasks. The organization that retained investigative services may have a specific framework that should be followed. This can serve as a guide through the investigative planning process. Investigative steps may include "intake, assignment, assessment of the allegation, creation and approval of the investigative plan by legal counsel, investigation, reporting, disciplinary action and remedial steps to improve internal controls and policy breakdown" (Biegelman and Biegelman 2010, p. 296). Potential witnesses may also be identified at this stage, as planning might be required to connect with those witnesses. However, more witnesses are likely to be identified as the investigation progresses.

The investigative steps in the plan may include identifying the goals of the investigation, the parties who need to be kept informed, the scope of the investigation, the investigation timeframe, the need for law enforcement assistance, operational issues, the course of action, and the necessary resources (ACFE 2014, p. 3.136).

The investigative plan should include a chronology of events, leading up to the fraud. This timeline should include details concerning the victim and suspects. Through this process, inconsistencies can be gleaned. Ultimately, a well-crafted investigative plan might reveal unexpected information. For instance, sometimes the "victim" is actually the fraudster (Giacalone 2015). For this reason, investigators should be sure to keep an open mind when analyzing the chronological data.

An investigative plan is a wise investigative tool. Planning the investigative process in advance can save time and money. The investigator may realize she/he needs additional people or assets to achieve investigative goals. This can be mapped out in the plan. However, the investigator will likely be working within a defined budget. As a result, there may never be enough time or money to accomplish all investigative goals. Compromises may have to be made. This can be realized during the investigative planning process.

Investigative plans may reveal the need for experts and/or technological resources. Experts might be required to advance a specific investigative goal. For instance, the financial expertise of an expert might be necessary to decipher complicated financial transactions. A technology expert and/or software package might be required to analyze encrypted data. These experts often come from the security and law enforcement industry (Pedneault et al. 2012, p. 121). It is important the expert be an ethical, trusted member of the investigative community, to ensure their findings are generally accepted. Upon completion of the plan, the investigator may want to prepare the organization for the upcoming investigation.

Investigation Process

Once the planning is complete, the investigation process may commence. While the general investigative process is similar across disciplines, there are some unique aspects to fraud/financial crime investigations (Pedneault et al. 2012, p. 124). Fraud investigations can be extremely complex. As the investigation progresses, and new information is learned, the investigation will constantly change and evolve (Pedneault et al. 2012, p. 124). As information is uncovered, the original investigative plan might require modification, which is customary.

During this learning process, the investigator develops the perspective from which they will ultimately examine their case. The ACFE advises fraud examiners to investigate fraud from two perspectives: (1) to prove that a fraud has occurred and (2) to prove that a fraud has not occurred (ACFE 2014, Section 3, P. 5). Both scenarios should be explored, in all instances. Why? Because legally, "proof of fraud must preclude any explanation other than guilt" (ACFE 2014, Section 3, P. 5).

Upon commencing a fraud investigation, the ACFE recommends using the "fraud theory approach" (ACFE, Fraud Examiners Manual,

p. 3.106). This approach entails analyzing the available data and developing a theory, or hypothesis, about what may have occurred, based on that information. Once developed, the hypothesis is tested by examining the available data to determine whether it can be proven. If not, that hypothesis is refined, and the process is replicated. As knowledge increases, the hypothesis and theories must be reevaluated (Pedneault et al. 2012, p. 124). It is possible that primary theories will turn into sub theories and alternate theories or may be refuted and become disproved hypotheses (Pedneault et al. 2012, p. 124). New theories may be developed. Ultimately, the hypothesis is continually revised and theory tested via data examination until a fraud is proven, or it is determined that the fraud cannot be proven. Ultimately it will be determined that no fraud was present, or a fraud will be confirmed.

To develop a working theory, investigators will want to gain background information (Pedneault et al. 2012, p. 126). If this industry is new to the investigator, she/he might begin by reviewing publications pertaining to the subject industry. This will allow investigators to develop a working knowledge of the general industry processes and terminology.

Evidence Collection

The general investigation will consist of evidence collection/exhibit preparation, witness identification, document identification, and analysis. Eventually, a suspect may be charged with a crime (Pedneault et al. 2012, p. 123). As a result, it is important to retain and collect evidence with care.

In the corporate setting, electronic evidence may need to be collected from the workplace. A suspect's business activities may require evaluation to determine whether fraud was present. The organization can provide the investigator with this evidence, as the business activities of the suspect/employee are not considered to be private when conducted using business computers/equipment. It is critical that electronically obtained information is obtained, collected, handled, and stored with extreme care. When in doubt, an electronic evidence expert should be contacted to assist (Pedneault 2009, p. 19).

It is important, especially in the corporate setting, to maintain strict confidentiality. Investigative allegations and documentation should be kept private to prevent leaks, reputational damage, tip-off to the fraudster, and erosion of employee confidence (ACFE 2014, p. 3.144). Information should be shared on a "need-to-know basis." Depending on the case, attorney work-product doctrine may apply to the documentary evidence. If the evidence is protected, the subject, government, and third parties may not gain access to this documentation (ACFE 2014, p. 3.148–149).

Electronic evidence may also need to be obtained from a worker's personal electronic devices. If the device was brought into the office, or owned by the organization, they should be involved in this process. Electronic evidence such as bank account activity, or private cell phone records on the part of the suspect, may also need to be obtained. Investigators should consult with the company and law enforcement partners to obtain such evidence, as subpoenas might be required and/or consent from the worker. A review of this evidence might reveal the names of additional witnesses and/or suspects that would not otherwise be gleaned from the available business records.

Additionally, investigators will want to examine the available business records. It is important for investigators to understand the business structure and process (Pedneault et al. 2012, p. 126). Helpful documents include organizational charts, internal policies, and corporate filings. Investigators might also create their own working flow charts, based on their understanding of the business records. In a fraud case, this process might be tedious, involving hundreds or thousands of documents (Johnston 2007, p. 569).

Follow the Money

Upon review, investigators should take note of how money flows within the organization. "Following the money" is an important fraud investigative technique. According to one expert, "the importance in following the money cannot be overemphasized. Whether the case is a simple bank fraud case or a complicated money laundering scheme, when one follows the money, you

will eventually ascertain who is the major player in the fraud" (Johnston 2007, p. 568).

To follow the money, investigators must determine, through a careful review of the financial records, the step-by-step path of the stolen money from "origination to its destination" (Johnston 2007, p. 569). Ultimately, prosecutors will need to demonstrate this process to the judge and/or jury. The prosecution has the burden of proof and must prove each element of the fraud case beyond a reasonable doubt (Johnston 2007, p. 569). Investigators should provide a detailed money trail, ending with the defendant (Johnston 2007, p. 569). Ultimately, the case should be presented to the jury in a "simple, polished and well-organized fashion" (Johnston 2007, p. 569). Visual aids are important in demonstrating the flow of money. Investigators should anticipate this and plan their investigations accordingly.

It is also critical for investigators to understand the parties in their case, including the potential suspect. Investigators can learn more about investigative subjects through the process of intelligence gathering. The intelligence gathering should include a background check on the victim (Giacalone 2015). Ultimately, the victim will be interviewed. The background check will provide the investigator with useful information in advance of the interview. The investigator may strategically choose to reveal or withhold certain intelligence learned during the background check process.

Investigators may conduct an interview of the victim, as part of the investigation. During the interview process, questions should be open-ended and address all of the investigative basics – who, what, where, when, how, and why. Overall, the investigator is looking for the victim to tell a story, and questions should be designed to elicit that story (Giacalone 2015). More detailed follow-up questions can be added later in the interview, to gain knowledge of specifics that may not have been covered during the victim's initial narrative.

Intelligence Gathering

The approaches for additional intelligence gathering include surveillance, database searches, and trash collection (Pedneault et al. 2012, p. 127–131). In a fraud investigation, surveillance can lead to information regarding banking and property ownership. Additional intelligence can be gleaned from Internet databases. Licensed private investigators may gain access to paid databases such as Delvepoint, IRB Research, and TLO which provide a wealth of information on subjects. As assets are uncovered, they may need to be secured, for the purposes of restitution (Pedneault 2009, p. 8).

There are also many publicly available databases that will provide useful information for the investigator. Both sources can provide information to confirm property ownership, including real estate holdings, criminal and civil litigation history, work history, and potential familial and business associates. Trash can also provide useful investigative intelligence. Before proceeding, investigators should check federal and state law. However, it should be noted that case law often sides with the investigator in these matters. While the location of the trash is important, generally speaking, trash is considered to be abandoned property (Pedneault et al. 2012, p. 130–131).

Overall, it is important for investigators to build a thorough and detailed case file. Jurors today have high expectations when it comes to fraud investigations, due to the "CSI effect" (Johnston 2007, p. 566). Specifically, according to prosecutors, jurors, whom have educated themselves in the investigative field via popular crime television shows, can have an inflated standard of proof in fraud matters. This happened during the HealthSouth Corporation fraud matter in 2005. Jurors said they wanted to see HealthSouth CEO Richard Scrushy's fingerprints on the document evidence (Johnston 2007, p. 566). Unfortunately, according to seasoned financial crime investigators, this is an impossible task (Johnston 2007, p. 566). One such expert, James B. Johnston, investigative supervisor at the Essex County Prosecutor's office in Newark, NJ, said he has "never, ever heard of a fingerprint impression having been taken off a piece of document evidence for a fraud case" (Johnston 2007, p. 566). Thus, although jurors might be ultimately disappointed with the evidence in a fraud matter, it is important to consider their high standard of proof when building one's fraud case.

Conclusion

Fraud investigations are detailed and specialized investigations. Careful planning is important to the success of the investigation. Thorough background research is required to conduct a detailed investigative plan. The planning phase helps investigators in determining the best approach. This phase culminates in a detailed investigative plan. The evidence collection process will ideally allow investigators to "follow the money" leading them to the source of the fraud. Intelligence gathering provides additional valuable evidence, which is well documented for potential litigation. Ultimately, a detailed case file is created. This case file is the culmination of a lot of hard work on the part of the investigative team. Special care should be used throughout the investigative process to ensure this file is as detailed, thorough, and accurate as possible.

Definition

Money laundering is the process criminals use to conceal and disguise the source, destination, or ownership of money and property earned through criminal activity.

Money laundering investigation is the process of identifying money laundering activity for the purpose of stopping it, reporting it to government, or prosecuting it.

Introduction

Money laundering exists because there are successful criminals. Many individuals and organizations commit crime for the purpose of making money, and a considerable amount of criminal activity is conducted for financial gain (OECD 2016). Some criminals are successful in this activity, which means they have the ability to accumulate profits and wealth from their illicit activity. With the prosecution of Al Capone in the 1920s, government realized that one method to identify and prosecute these successful criminal individuals and enterprises was by "following the money." After that, criminals learned they needed to hide and disguise this illegitimate income. The cat-and-mouse investigative game of money laundering – and the investigation of it – was born. Both the government and private sector play significant roles in this investigative process.

In 1986, government realized existing laws were inadequate to address the concealment of illicit income and assets, so criminal money laundering statutes were enacted. Government recognized that it alone could not monitor and investigate financial activity adequately, so duties and responsibilities were placed upon the private sector to detect and combat money laundering. Government created a regulatory and licensing framework to try ensure that only licensed and supervised financial institutions and money service businesses (MSBs) conducted financial transactions on behalf of customers. If individuals seeking to transfer or store funds use banks and money transmitters who are complying with government regulations, then their transactions and activities are being monitored. Government effectively deputized financial institutions to monitor their customers and transactions for suspicious activity that is indicative of money laundering, terrorist financing, or other criminal activity. Entities who fall short on their anti-money laundering (AML) monitoring and reporting can face significant governmental consequences, to include civil fines, loss of license, and even criminal prosecution. If a financial institution loses its license, it cannot continue in business.

In the United States, the Financial Crimes Enforcement Network (FinCEN) is an arm of the Treasury that has responsibility for AML, counter terrorist financing (CTF), and sanctions programs. Sanctions are administered through the Treasury's Office of Foreign Assets Control (OFAC). The anti-money laundering arena overlaps with other areas designed to monitor and restrict the flow of funds. CTF programs seek to restrict and trace the flow of funds to and from terrorists and their organizations. Sanctions programs seek to restrict the ability of individuals, organizations, and nation states who are the subject of sanctions to move and hold funds.

The investigation of money laundering has been, and continues to be, an evolution of laws, regulations, techniques, methods, and technology. On one side are individuals and entities seeking to conceal and disguise funds – criminals, terrorists, sanctioned individuals and countries, or just individuals trying to avoid paying taxes. On the other side are the investigators, regulators, and prosecutors trying to detect this activity. This includes the government and also financial institutions who have invested in AML programs and personnel.

What Is Money Laundering?

As the definition indicated, money laundering is the process of concealing and disguising information about funds earned through criminal activity. It concerns hiding information about one or more aspects of property, such as how it was earned, where it came from, who owns it, and where it is going. It is what prosperous criminals must do in order to maintain their ill-gotten gains and escape punishment. If society wishes to effectively fight the many financial crimes that victimize law abiding citizens, then it needs to address money laundering. Typically, money laundering is described as a three stage process: placement, layering, and

integration (UNODC website, Department of the Treasury, National Money Laundering Risk Assessment 2015).

Placement occurs after criminal activity generates profits, which needs to be placed into the financial system. If the illicit income is cash, then depositing the cash into a bank might constitute placement. Today, large quantities of cash attract unacceptable attention, so cash placement must be done unobtrusively. The criminal could mix the cash with legitimate income from a business that is cash intensive, such as a restaurant, barber shop, pizza parlor, car wash, or other business. Placement could be accomplished through "smurfing," where large amounts of cash are distributed to many individuals ("smurfs"), and all of the individuals deposit small amounts of cash into their respective bank accounts.

Layering is a money laundering process that attempts to disguise and obfuscate the initial placement and true source of the funds. Think of layers of a rotting onion, with each layer concealing the rot within the core. Each layer helps to conceal what is beneath it, so that corrupt income can appear legitimate. One way to layer funds would be to repeatedly transfer money through several shell corporations and countries, another would be to disguise illicit income as the result of a sham transaction, loan, or investment.

Integration is the final money laundering stage where the criminal reaps the illegal reward, such as through the purchase of a home, business, or other investment or asset with funds that appear to be legitimate, untainted by criminal activity. The criminal is now the lawful owner of an asset, with all the accompanying rights.

These three stages are not rigid steps, since the creativity of the criminal is not restricted by definitions and typologies. Further, these stages are well suited for many cash money laundering situations, but with cybercrime and virtual currency new dynamics present themselves. When analyzing money laundering as a criminal offense, remember that terms are specifically defined within the relevant federal or state statute. To commit the crime of money laundering, a person needs to perform specific acts with the appropriate mental state as defined in the particular statute. Generally, someone has committed the crime of money laundering if he or she know funds are criminal proceeds, and conducts financial transactions with these funds for the purpose of concealing or disguising their source, destination, or ownership. (See for example, §§ 18 U.S.C. 1956, 1957). Additional information on criminal statutes appears in the subsequent section "Money Laundering Criminal Statutes."

Who Investigates Money Laundering?

Many different types of organizations investigate money laundering, financial transactions, or the ownership of assets, where facts are not readily apparent or are concealed. Examples include law enforcement, intelligence agencies, regulators, financial institutions, private individuals, journalists, and non-profit organizations. The Treasury Department's Bureau of Financial Crimes Enforcement Network (FinCEN) is a clearing house for financial data and analysis, which is used for both criminal enforcement, regulatory, and intelligence purposes. It is the financial intelligence arm of the US Government, with a mission to keep the financial system from being used for illegal purposes and to promote national security.

Law enforcement investigates suspected violations of criminal money laundering statutes. These investigations are typically complex, so federal law enforcement plays a predominant role in this area. Federal agencies that investigate money laundering include the Federal Bureau of Investigation (FBI), Drug Enforcement Administration (DEA), Internal Revenue Service (IRS), Department of Homeland Security (DHS), and United States Secret Service (USSS). Violations of federal law are ultimately prosecuted by United States Attorneys (federal prosecutors). State and local law enforcement can also investigate violations of state money laundering laws. The offices of the Attorney General of each state may have the resources to conduct investigations of this type. Some local prosecutors' offices also conduct

significant money laundering investigations and prosecutions, such as the New York County District Attorney's Office. Agencies with a role in protecting the country's national security also analyze financial transactions, including the Central Intelligence Agency (CIA), FBI, DHS, and others. Financial transactions might help reveal nation state espionage, participants in a terrorist cell, or that a nation is evading sanctions.

Financial institutions investigate money laundering. They are required to have anti-money laundering programs which include a compliance officer, policies, procedures, staffing, and tools (see subsequent section on regulation). They need to have adequate ability to detect and investigate suspicious financial transactions, report upon them as required, and properly document their actions. This duty has created the AML profession, designed to keep the institution in compliance with laws and regulation, and to keep the institution from being used as a tool by criminals and money launderers. As a part of these requirements, financial institutions must continually search for and identify money laundering activity, and where found report it to regulators and law enforcement via suspicious activity reports ("SARs") as discussed in the subsequent section. Law enforcement can then investigate – and where warranted and their limited resources allow – bring criminal prosecutions. Financial institutions can terminate relationships with customers whose activity is illegal or suspicious. Government regulators also investigate money laundering and monitor the financial institutions that they supervise to ensure that *they* are properly investigating money laundering. Financial institutions have been deputized by the government to monitor their customers, and regulators are watching the watchers to ensure this is done properly.

Private individuals sometimes probe money laundering. Consider a victim who suffers millions of dollars of damage or losses due to a wrongdoer's theft, misconduct, or negligence. That victim may hire an attorney or otherwise seek a court order directing the wrongdoer to return the funds. The wrongdoer may attempt to hide assets in order to keep them from being seized and may use money laundering techniques. The victim or attorney may hire investigators to try trace and recover funds, to try locate and seize the assets. This investigative process seeks to locate the hidden assets, establish facts that would allow an appropriate court to freeze the assets, and ultimately direct their delivery to the victim. Similarly, journalists scrutinize financial relationships and transactions which may be obscured using money laundering techniques. The phrase "follow the money" was associated with the Washington Post's investigation of President Nixon's Watergate scandal in the early 1970s (All The President's Men 1976). Investigation of financial transactions surrounding Watergate helped piece together who was involved and the breadth of their activities. Many investigative journalists realize the value of financial analysis to uncover facts, motivations, or connections. Examples of nonprofits conducting this type of investigative journalism include Global Witness, the International Consortium of Investigative Journalists, and the Organized Crime and Corruption Reporting Project.

Criminalization, Regulation, and Investigation of Money Laundering

Money laundering has a relatively recent origin as a distinct crime – it was not until 1986 that the first money laundering criminal statute was enacted in the United States, The Money Laundering Control Act, 18 U.S.C. §1956 and §1957. However, the underlying conduct was occurring long before it was explicitly criminalized. Ever since governments have taxed their citizens, some have responded by hiding their money and wealth. Consider Al Capone, the notorious crime boss who settled in Chicago and led the "Outfit" in the 1920s. He led a criminal enterprise that profited handsomely from illegal alcohol transportation and sales (bootlegging), prostitution, and extortion during the prohibition era. To keep his illegal businesses in operation, a host of other crimes were committed, including bribery of public officials, intimidation, assault, and murder. The most serious of these crimes were never successfully prosecuted, perhaps due to witness

intimidation, lack of cooperation, corruption, or an absence of legal tools necessary to hold the crime boss responsible for the physical acts of his employees. Instead, it was tax fraud that ultimately caused Capone's downfall. He did not report his income to authorities, and neither did he sufficiently conceal it, living extravagantly with his riches. Prosecutors proved his failure to report income, and he was sentenced to 11 years prison.

The lesson of Al Capone was not lost on organized crime – unreported income can give rise to prosecution for tax fraud which can mean prison. Further, government might not be content with charging tax fraud. Tracing funds between source and destination might demonstrate the full criminal conduct of the defendant, a leader and profiteer of a criminal operation. To avoid arrest, smart criminals had to disguise some of their illicit criminal proceeds as legitimate income and report this income on their tax returns. Without documented income, they cannot explain expenditures for dinners, cars, boats, and homes. The income must have an appearance of legitimacy, because if the stated activity is truthful they would convict themselves. The tactic of money laundering allowed criminals to earn seemingly legitimate profits, while keeping law enforcement from tracing its true origin. However, it would take more time until government realized this practice needed to be criminalized.

To make criminal profits seem legitimate, "dirty cash" needs to be introduced into the financial system. Dirty cash is inconvenient for many reasons: it is bulky, attracts attention and risk of theft, is hard to store long term, and cannot be used to purchase expensive items such as businesses, houses, cars, and boats. Depositing cash into a bank account allows the criminal to use the financial system to store and transfer funds. Before enactment and proper enforcement of AML laws, criminals might bring tens of thousands of dollars of cash to the bank, deposit it, have their accounts credited, and then funds could be sent by check or wire. Few questions were asked, no reports were filed, and bank employees might have had knowledge about the criminal origin of the funds.

The Bank Secrecy Act of 1970 (BSA) introduced controls to stem this activity, and required financial institutions to detect and report money laundering activity. No longer could a duffel bag of cash be brought to the bank branch and deposited without questions being asked, and without reports being filed. Through the BSA, as it has been periodically amended, banks and many businesses are now required to report cash transactions of $10,000 or more through currency transaction reports (CTRs). They also must detect and report activity indicative of money laundering or other criminal activity through suspicious activity reports (SARs). Failure to make these reports could result in civil and criminal penalties for the bank.

The Money Laundering Control Act of 1986 was another important milestone, marking the first time that the federal government criminalized money laundering. It created new statutes: 18 U.S.C. §1956 and §1957 which made it a federal crime to conduct financial transactions with known criminal proceeds. Many states soon followed with their own money laundering statutes. These laws applied not just to criminals who launder their own ill-gotten gains but to third parties who perform money laundering services for them.

Over the years, there have been various amendments to these laws, including the USA PATRIOT Act of 2001, enacted in response to the terrorist attacks of 9/11. This statute strengthened financial monitoring and penalties, required banks to establish AML and CTF programs, designate a responsible compliance officer, create written policies and procedures, train employees, and obtain an independent audit. Despite the development of laws and regulations, they did not stop money laundering. Instead, criminals continue to seek and develop methods to disguise their activity and evade detection. Investigators need to keep up with emerging trends in order to detect and prosecute offenders.

Virtual currencies – also called digital currencies and sometimes called cryptocurrencies – present new money laundering investigative and regulatory challenges. Most readers have heard of the popular virtual currency Bitcoin. Virtual

currency laundering methods are quite different from cash laundering, since virtual currency is earned, stored, and spent very differently. Criminals, including cybercriminals and identity thieves, have recognized the benefits of virtual currencies for paying each other and for laundering funds. From the creation of the first virtual currency in 1996 until 2013, it was ambiguous as to whether regulation applied to virtual currencies (Bandler, Cybercrime and Digital Currency 2016, p. 9). In 2013 FinCEN made clear that AML and registration regulations did indeed apply to virtual currency issuers and exchangers. However, the effect of this regulatory requirement was limited with the invention of and rising popularity of decentralized cryptocurrencies such as Bitcoin. Virtual currencies can be categorized as centralized or decentralized, where centralized currencies are administered by an entity, and decentralized currencies are typically cryptocurrencies, since it is the blockchain technology pioneered by cryptocurrencies that allows transactions to take place without a central administrator (Bandler, Cybercrime and Digital Currency 2016, p. 3, and ACAMS CAMS Certification Exam Study Guide sixth Ed. 2016, p. 65). With decentralized virtual currencies, there is no central currency administrator to implement an AML program or be held accountable for failing to do so. Thus a review of exchangers and users becomes all the more important. All virtual currencies present money laundering risks because of user anonymity, cross-border value transfer, and limited compliance with regulations and laws. Although virtual currency presents many crime and money laundering risks, investigators should remember that all conventional financial systems and methods also present these risks.

Money Laundering Laws and Regulations

Money Laundering Criminal Statutes

Federal and state criminal statutes prohibit money laundering activity. The applicable federal statutes arose from the Money Laundering Control Act of 1986 as 18 U.S. Code § 1956 (Laundering of Monetary Instruments) and 18 U.S. Code § 1957 (Engaging in monetary transactions in property derived from specified unlawful activity).

18 U.S.C. §1956 provides for penalties of up 20 years federal prison and fines of up to one half million dollars or twice the value of the funds. There are three subdivisions of the crime. Subdivision one sets forth that a person commits money laundering when they have knowledge that property is proceeds of unlawful activity, they conduct financial transactions with these illicit proceeds, and they (i) intend to promote or further more illicit activity, (ii) intend to commit tax fraud, (iii) are trying to conceal or disguise the location, source, ownership, or control of the property, or (iv) are trying to avoid a reporting requirement about the transaction. The transaction "reporting requirements" the statute refers to include the filing of CTRs and SARs, so someone who makes daily cash deposits of $9,000 in criminal proceeds to avoid the $10,000 threshold for the filing of a CTR would have committed money laundering.

Subdivision two of 18 U.S.C. §1956 criminalizes transfer of funds across US boundaries with knowledge that the funds are criminal proceeds, if the transfer is with the intent to avoid a transaction reporting requirement or to conceal or disguise the nature, location, source, ownership, or control of the funds. Bulk smuggling of cash criminal proceeds across the border, or sending a bank wire to disguise the criminal proceeds would be examples of this.

Subdivision three of 18. U.S.C. §1956 is designed for undercover law enforcement "sting" operations. This subsection does not require that the funds *actually* be criminal proceeds, but rather that they were "believed to be" or "represented to be" criminal proceeds. The undercover agent pretending to be a drug dealer who delivers $100,000 in cash to a corrupt businessman or financial advisor may be laying the foundation for a prosecution under this section.

States have statutes that criminalize money laundering. For example, New York State criminalizes money laundering within Article 470 of the state Penal Law. In essence, it is similar to the federal money laundering statute, but it is broken

down into four distinct degrees, distinguished by the amount of funds laundered. Then each degree has multiple subdivisions. Critical aspects include whether the property is the proceeds of criminal conduct, the defendant's intent to promote the carrying on of criminal conduct or engage in tax fraud, and the defendant's knowledge as to whether transactions are designed to conceal or disguise the nature, location, source, ownership or control of criminal proceeds, or avoid reporting requirements.

Money Transmitting Regulations and Criminal Statutes

Every state in the United States except for Montana requires money transmitters within their borders to be licensed by the state. This means that companies within the state in the business of transmitting funds on behalf of customers must submit to state licensure and regulation requirements. Examples of money transmitters include Western Union, MoneyGram, and PayPal.

Consider New York State's Banking Law § 650 (Unlicensed Money Transmitter), which holds that a person or entity who is in the business of sending or receiving money without a license is guilty of a misdemeanor. If the funds exceed certain thresholds – such as $25,000 per month or $250,000 per year – are criminal proceeds – then the offense rises to a felony. With the license come responsibilities to create and maintain records and have an AML program.

Federal law bootstraps upon state money transmitting laws. The federal government can prosecute individuals or entities under federal law if they violate a state money transmitting law. 18 U.S. Code § 1960 (Prohibition of unlicensed money transmitting businesses) criminalizes anyone who knowingly conducts, controls, manages, supervises, directs, or owns all or part of an "unlicensed money transmitting business." An "unlicensed money transmitting business" is one that transfers funds on behalf of customers by any means and either (i) lacks a state money transmitting license where such license is required or (ii) fails to register with the Treasury Department as a money transmitter. *See* 18 U.S.C. § 1960. The registration requirement is set forth in 31 U.S.C. § 5330 (registration of money transmitting businesses).

Thus, compliance with various money transmitting laws requires obtaining a state license, registering with the federal government as a money service business (MSB), creating and maintaining records about the business, customers, and transactions, maintaining an anti-money laundering (AML) program, and reporting required events to FinCEN.

Licensing and Regulation of Financial Institutions

Banks and other financial institutions are common mechanisms for people to store and transmit funds. Like money transmitters, Banks are regulated and licensed. Financial institutions need to be licensed by the state in which they operate, register with the federal government, and are subject to state and federal oversight. They may be supervised by one or more federal organizations, such as the Federal Deposit Insurance Corporation (FDIC), Office of the Comptroller of Currency (OCC), National Credit Union Administration (NCUA), Federal Reserve Board (FRB), the Consumer Financial Protection Bureau (CFPB), and FinCEN. State authorities may regulate the bank as well, such as New York's Department of Financial Services.

This licensing and oversight has many purposes, including consumer protection, ensuring the stability of the bank and the financial system, and also anti-money laundering controls (CFPB website, FDIC website, and FinCEN website). Regulations require the institution to have an AML program, which basically means that the bank has policies, people, and systems watching for suspicious transactions and activity indicating criminal activity, money laundering, or terrorist financing.

FinCEN and their Role in AML and Regulation

As mentioned earlier, FinCEN is the bureau within the Treasury Department charged with keeping criminals, money launderers, and terrorists from using the financial system, and with obtaining intelligence from financial transactions.

Under the Bank Secrecy Act (BSA) and USA PATRIOT Act, banks and money transmitters are required to look for suspicious activity and large cash transactions and report it to FinCEN through SARs and CTRs. Every financial institution, money transmitter, and money service business in the USA must comply with regulations, and this includes having an AML program and filing these reports when required. These regulations apply to not only financial institutions but to car and boat dealers, casinos, and art and jewelry dealers. Any business that receives over $10,000 in cash in connection with a transaction needs to file IRS form 8300 with FinCEN or the IRS. All of this information that FinCEN keeps is tightly controlled, and unauthorized disclosure is a serious criminal offense. FinCEN's information is used by criminal investigators and prosecutors at the federal and state level, and by our national security apparatus.

The AML Program

The laws and regulations designed to keep the financial system clean requires that financial institutions and money transmitters have an AML program (Bank Secrecy Act). This means they must create policies, procedures, systems, and employ people to monitor customers, the funds they store and transmit, and investigate potential money laundering activity. It also means that if they fall short of their responsibilities, there can be serious consequences, to include civil fines, criminal prosecution, and loss of license.

The AML program starts with learning who the customer is and what their business is. This is known as "know your customer" (KYC) and customer due diligence (CDD). It requires training employees such as bank tellers and relationship managers to look for signs of money laundering, and it means monitoring all transactions, which might require using special software designed to detect patterns and relationships.

When customers make large cash transactions, such as over $10,000, a currency transaction report (CTR) needs to be filed with the government that includes customer information. The bank would need to evaluate if this cash transaction is in accord with the customer's expected legitimate banking activity. When customers behave suspiciously, or in a manner to indicate criminal activity, the bank has a duty to investigate, and report this suspicious activity to FinCEN as a suspicious activity report (SAR).

For example, suppose a customer tells the bank he is unemployed, yet he regularly deposits large amounts of cash into his account. The bank would be required to investigate this, and probably report it via a SAR. If the customer deposits $9,999 in cash on two separate days, that might not require the filing of a CTR, but it might require the filing of a SAR, because the customer appears to be structuring deposits to try avoid having a CTR filed. If the customer states that he is involved with selling merchandise on eBay, but deposits large volumes of cash, or receives high dollar bank wires, that would be worthy of further investigation. If a customer is a victim of a fraud, or is a participant in a fraud, the bank's AML personnel need to investigate, and probably file a SAR.

All of these CTRs and SARs go to FinCEN and are accessible to certain law enforcement throughout the country. As indicated previously, the information filed with FinCEN is secret, and unauthorized disclosure is a serious criminal offense. Government and bank employees are not allowed to disclose their filings, nor even the fact that a filing was made. Thus, while it is well known that SARs need to be filed, it is a crime to disclose the filing of a particular SAR. Thus it would be improper to ask someone to disclose this information.

Money Laundering Typologies and Examples

The money laundering investigator should be aware of various typologies, some of which are summarized here, keeping in mind that the criminal's creativity is unbounded by existing frameworks. After all, typologies are merely criminal conduct that has been discovered and written about. Imagine the criminal conduct that has not yet been identified.

Typologies

Structuring is the process of breaking up one payment into smaller, less-recognized payments to avoid reporting requirements. (31 U.S.C. § 5324, Dept. Treasury National Money Laundering Risk Assessment 2015, ACAMS Study Guide p. 20). If the drug dealer desires to deposit $50,000 in cash into the bank, he might chose to do that $5,000 per week, for 10 weeks, thus structuring the deposits to avoid reporting requirements.

Smurfing is similar to structuring, but it involves using many people to disguise the transaction (FATF Report on Money Laundering Typologies 1998, ACAMS Study Guide p. 20). If the drug dealer desires to deposit $50,000 in cash to a bank, he could give $5,000 to ten of his employees or associates, who deposit it into their own bank account. Then they each make a payment to the drug dealer by check or wire.

Bulk cash smuggling is used to avoid cash reporting requirements at the border. (31 U.S.C. § 5332, Dept. Treasury National Money Laundering Risk Assessment 2015, p. 27, ACAMS Study Guide). The USA requires individuals transporting over $10,000 across the border to report this, but criminals cannot declare their cash, so it is hidden on their person, in their luggage, or in the vehicle. Drug traffickers who smuggle drugs into a country may use similar techniques to smuggle cash profits out of the country.

Trade-based money laundering uses the ruse of an international transaction to transfer value secretly from one place to another (Dept. Treasury National Money Laundering Risk Assessment 2015, p. 29, ACAMS Study Guide p. 55). This can be done through fictitious invoicing, over-invoicing, and under-invoicing. With a fictitious invoice, Company A provides an invoice to Company B, but no goods or services were really provided. Company A receives payment from Company B, and the funds appear legitimate. With over- or under-invoicing, Company A provides goods or services to Company B, but the invoice is either much higher or lower than the value provided. When Company B pays Company A, net value is transferred but the amount and direction of transfer is disguised.

Shell companies disguise the true ownership and control of the company (Dept. Treasury National Money Laundering Risk Assessment 2015, ACAMS Study Guide). The criminal uses a shell corporation, ABC Corp, so that the account is not in his true name. It is hard to identify the owners and directors of ABC Corp, because it, in turn, is owned by XYZ Corp. Where incorporation documents were filed with the government, they were filed by a business that protects the confidentiality of its clients. Shell corporations may be incorporated on one country, but use bank accounts in another country, picking countries that provide confidentiality. *Front companies* are a variation on this theme, where an ostensibly legitimate business is merely a disguise for money laundering or other nefarious activity.

Salaries can be used to launder funds (ACAMS Study Guide p. 70). A criminal may be on the payroll of a company and is paid a salary as if he works there, but in fact does not. Or, companies might pay employees in cash derived from criminal proceeds.

Attorneys and accountants may be used by money launderers, wittingly or not, to launder funds (Dept. Treasury National Money Laundering Risk Assessment 2015, ACAMS Study Guide p. 148). A tiny percentage of these professionals use their expertise unlawfully by actively assisting criminals with the commission of crimes such as money laundering and tax evasion, by giving advice on how to commit crimes and escape detection. Some may inadvertently provide services that assist criminals with shielding assets or transactions from government view. Of course, the vast majority of attorneys and accountants are honest, giving ethical advice to law abiding clients including about how to comply with laws and regulations.

Real estate can be used as a vehicle for money laundering (Dept. Treasury National Money Laundering Risk Assessment 2015, ACAMS Study Guide). Where funds are sent or received from shell companies, property is owned by a shell company, or attorneys are used to send or

receive funds on behalf of the client; there is the ability to disguise the true ownership, source, or destination of funds.

Cybercrime has created new money laundering typologies (Dept. Treasury National Money Laundering Risk Assessment 2015, Bandler, Stemming the Flow of Cybercrime Payments, ACAMS TODAY, June 9, 2017). Cybercrime is conducted through the internet, making cash an inconvenient payment mechanism. Virtual currencies (e.g. Egold, Liberty Reserve, or Bitcoin) have become a payment method of choice between criminal participants. Cybercrime is tied to identity theft and also involves theft of funds in a variety of formats, including through bank wire, forged checks, and credit or debit accounts.

Money mules are recruited by cybercriminals to move money on their behalf (Dept. Treasury National Money Laundering Risk Assessment 2015, Bandler, Stemming the Flow of Cybercrime Payments, ACAMS TODAY, June 9, 2017). These money mules, wittingly or not, receive forged checks and misdirected bank wires, and send the funds to the next destination on behalf of criminals. Cybercriminals are constantly recruiting these money mules, through work-at-home scams, romance scams, or sophisticated schemes that purportedly involve collecting a debt or otherwise receiving a payment.

Traditional business can be created or coopted for the purpose of receiving criminal proceeds, for making payments which appear to be legitimate, and which can even be reported on taxes (Dept. Treasury National Money Laundering Risk Assessment 2015). Suppose the drug kingpin earns over a million dollars in cash per year – more cash than he can use or store himself. He reaches an agreement with a restaurant owner, and he gives the restaurant owner $20,000 in cash every month. The restaurant owner makes regular bank deposits for the day's cash receipts and includes a portion of the drug dealer's cash with each deposit. The bank and tax authorities are told this is restaurant income, though it is mostly drug dealing income. The restaurant's bank balance swells each month, and the drug dealer receives a monthly check for $10,000 under the guise he is a part owner, a salaried employee, or a vendor of supplies or services to the restaurant. Ultimately, the drug dealer might want to launder more funds, so he could buy – or create – businesses to use as front companies to do this.

Investigation Considerations

The money laundering investigator should consider how the criminal profits are earned, how criminals pay each other, do business, and reap the benefits. In other words, think like the criminal. The investigator should not only "follow the money" but also "follow the product," because this will give insight about where the money is going. Monetary transactions accompany transfer of contraband and criminal services (Bandler, Lawyers, Drugs and Money, AML in Popular Media 2018). After all, criminals do not provide goods or services for free, they are doing it to get paid. For example, suppose drugs are grown and manufactured in South America, and delivered to various cities in the United States, and then sold on the streets for cash. The drugs follow a path through farming, processing, shipment, repackaging, and sale, and many people play a role at each stage of this process. The drug "kingpins" within the United States and South America are reaping significant profits, and beneath them are a wide spectrum of employees, workers, and contractors, some of whom earn handsomely while others earn a pittance. The sale of the drugs on the street is done for cash, the street dealer and team are paid, give cash to their boss, and so on up the chain. Much of that profit needs to ultimately make its way back to the country of drug origin to pay the kingpin, traffickers, and laborers. Perhaps cash is smuggled to South America, or perhaps funds are sent via bank wire of virtual currency. Funds need to be transferred in a manner that is cost efficient, safe, and hidden from government detection.

Cybercrime Money Laundering

Cybercrime has altered the traditional money laundering models, since illicit profits are often earned in virtual currency rather than cash, presenting different money laundering challenges for

the criminal, and a different typology for law enforcement, regulators, and private investigators (Bandler, Stemming the Flow of Cybercrime Payments 2017). Law enforcement is still learning how to effectively address cybercrime and how it launders funds. Here is an example of cybercrime money laundering: A hacker from another country hacks into a US-based company and steals millions of records, such as credit card account information, credit report information, internet usernames and passwords, or other victim information. The hacker sells this information to a "vendor" of stolen data, who pays for the data in virtual currency. Next, the vendor sells this hacked data to identity thieves in the USA, who also pay with virtual currency. The identity thieves work with their associates to commit identity theft, to create forged identification and credit cards, to assume the identity of the victims, use their credit to purchase merchandise or otherwise steal. These participants never meet each other, never learn each other's true name, but still need to pay each other. Cash is of little use, but virtual currency works perfectly. The cybercriminals earn prodigious profits in virtual currency and need to launder those funds.

Prosecution Examples

Since the creation of money laundering criminal laws, there have been many prosecutions of those who hid their own illegal profits, as well as those who facilitated their activity. Financial institutions can be held liable both criminally and civilly for their customers' activity. In the early 1990s, it was discovered that the Bank of Credit and Commerce International (BCCI) was involved with massive money laundering and fraud and were charged federally in Florida and with state charges by the New York County District Attorney's Office. BCCI ultimately pleaded guilty in state and federal court and forfeited over a half a billion dollars and went out of business. In 2014, BNP Paribas pleaded guilty to falsifying business records in a scheme to illegally move funds on behalf of sanctioned individuals and entities, and paid nearly nine billion dollars in penalties but remained in operation. In 2012, HSBC entered into a deferred prosecution agreement with state and federal authorities and paid nearly two billion dollars in fines for falsifying records, laundering funds on behalf of drug traffickers, and transmitting funds for sanctioned entities. Other banks have been fined by federal and state regulators for falling short with their AML requirements.

As mentioned, cybercrime launched a new era in crime and money laundering, including through virtual currency. Egold was the first virtual currency, invented in the mid-1990s, and became popular with cybercriminals and identity thieves. In 2007, Egold was charged by federal authorities of money laundering and illegal money transmitting and was convicted by guilty plea in 2008.

Western Express International, Inc. was a virtual currency exchanger based in Manhattan which facilitated cybercrime and identity theft related conduct, and laundered funds for its customers. In an investigation that spanned from 2005 to 2013, the New York County District Attorney's Office investigated the exchanger, followed the money (digital currency), and ultimately identified many of the exchanger's clients. Cybercriminals were extradited from Eastern Europe, identity thieves were arrested across the USA, and the exchanger and its owners were also charged. Most defendants admitted their responsibility through guilty plea, and the remaining three were convicted after a trial that lasted over 2 months. This case provided a window into the global nature of cybercrime, virtual currency, and money laundering techniques through digital currency, money remittances, bank wires, and shell corporations.

Liberty Reserve was a virtual currency based in Costa Rica, which also catered to criminal conduct by cybercriminals, identity thieves, and others. In May 2013 the business and owners were indicted by federal authorities, and they were ultimately convicted by guilty plea of money laundering. The prosecution of Silk Road mastermind Ross Ulbricht marked another successful cybercrime money laundering case. Ulbricht had created and operated an online marketplace for drugs and other contraband, where participants paid each other with Bitcoin virtual currency. The public is interested in crime stories,

so money laundering investigation has found its way into television and movies, including the television series The Wire, Breaking Bad, Ozark, and more (Bandler, Lawyers, Drugs and Money, AML in Popular Media, March 20, 2018).

Anti-Money Laundering Organizations

There are a number of organizations that address or focus on anti-money laundering issues, including international, governmental, non-profit, and for-profit trade organizations. Every country's financial intelligence agency (e.g., FinCEN) can join with the international Egmont Group of Financial Intelligence Units, which promotes cross-border cooperation with financial investigations. The Financial Action Task Force on Money Laundering (FATF) is an inter-governmental organization devoted to combating money laundering, terrorist financing, and other threats to the international financial system. The United Nations has devoted resources toward anti-money laundering, established the Office on Drugs and Crime, and offers model legislation that countries may choose to adopt. The Association of Certified Anti-Money Laundering Specialists (ACAMS) is the largest international membership organization dedicated to anti-money laundering and administers a professional certification. There are also other professional organizations for AML professionals. Other organizations and resources are listed in the additional reading section.

Conclusion

Money laundering investigation is conducted by many participants from the government, financial, private, legal, and journalism sectors. Through proper investigative techniques, criminal activity and profits can be identified and minimized. Legal and regulatory requirements may impose a duty to adequately detect and investigate money laundering activity.

Investigations: Negligence

Thomas Shea
Police Graduate Studies Program, College of Education and Human Services, South Orange, NJ, USA

Keywords
Investigation · Negligence · False confessions · Exclusionary rule · Wrongful convictions · Entrapment · Failure to train · Failure to supervise

Definition

This entry focuses more on a singular form of occupational obligation failure, that is, investigation negligence. These failures occur because of various reasons, including the following: neglect of duty, oversight, incompetence, and recklessness. Investigation negligence has the potential

to affect court dispositions, incarcerate the innocent, and cause unnecessary stress and trauma to already suffering crime victims. Additionally, there remains a causal and replicated link between investigation negligence and costly litigation expenses incurred by police departments in the United States. Training and proper supervision are employed to mitigate the adverse effects of investigation negligence, yet a prevalence still occurs.

Introduction

Negligence is defined as, "a failure to behave with the level of care that someone of ordinary prudence would have exercised under the same circumstances. The behavior usually consists of actions, but can also consist of omissions when there is some duty to act (e.g., a duty to help victims of one's previous conduct) (http://www.law.cornell.edu)." All behavior based on forecasts instead of results creates some level of potential harm, causing risk (Gilles 2000). Negligence, on the other hand, is unjustifiable risk, or actions that a reasonable person would not undertake given the same circumstances (Model Penal Code 2.02(2)(d)). When risks are unjustifiable and the justifications for taking them are minimal, negligence become "gross" (Moore and Hurd 2011). Investigation negligence presents during various aspects of investigation, but those affected as a result have the propensity to be detrimental.

According to Rossmo (2009), there are three primary causes leading to the investigative failures due to negligence: cognitive biases, organizational traps, and probability errors. Cognitive biases include memory limitations that lead mental errors due to the simplification of information processing (Heuer 1999). The memory of an average human being only holds a certain amount of information, ultimately leading to a false supporting of our hypotheses (Schacter 2001). Organizational traps include rumors and ego, among other aspects (Rossmo 2009). Rumors and misinformation negatively impacts the trajectory of investigations, leading to many well-known cases to venture down erroneous directions (Campbell 1996). Ego often causes the failure of an investigator to adapt to the acquisition of new, dissenting information (Rossmo 2009). Differing word meanings vary between the message sender and the receivers (Heuer 1999). Probability errors in judgment and decision making are often the result.

Investigative Mistakes

Discounting of pertinent information is precipitated by behavior such as anchoring, selective perception, and "onus probandi," transference of the burden of proof to the suspect instead of the investigator (Ditrich 2015). While not permissible in a court setting, there are plenty of opportunities to occur in the investigative field. Anchoring involves the overestimation of uncorroborated, partial evidence; even when new evidence disputes its legitimacy. Validation of inconsistent evidence undermines accuracy because evidence that challenges chosen hypotheses is disregarded (O'Brien 2009). Subsequently, "attractive" subjects may emerge from the formation of biased opinions of investigators, who consider high the likelihood that they committed the crimes investigated (Saladin et al. 1988). Judgments concerning the accountability of certain suspects are thus stronger as a result (Sigall and Ostrove 1975), whether correct or not. "Innocent until proven guilty" is a fundamental, Constitutional right in the United States; yet, both inter- and intraorganizational pressures may compel investigators to solve cases hastily, thus causing the aforementioned mistakes (Krix and Sauerland 2011).

Results of Investigative Negligence

False Confessions

Negligent investigation can result in false confessions, causing the true perpetrator to remain unapprehended and free to commit additional crimes (Doyle 2010; Russano 2004). Although more attention has been recently focused on this issue, the fact remains that a

large number of criminal convictions are the outcome of false confessions (Dwyer et al. 2000; Kassin and Neumann 1997; Rattner 1988). Kassin and Wrightsman (1985) identified three types of false confessions: (a) coerced compliant false confessions, (b) voluntary false confessions, and (c) coerced-internalized false confessions. Other researchers (Kassin and Gudjonsson 2004) examined a large amount of data including case studies, field experiments and correlational reports. They concluded that police interrogation tactics will likely continue producing false confessions.

False Witness Statements

Many false confessions are the byproduct of incorrect or false statements from witnesses; in fact, three quarters of hundreds of subsequent false confessions originated from false witness statements (Garrett 2011). The revelation of this dilemma led to a resurgence of the use of expert witnesses by defense attorneys in court, to refute the reliability of false statements (Loftus 2013). Newring and O'Donohue (2008) conducted a study resulting in findings implicating the fact that police are following investigative leads based on false statements, some of them unintentionally.

Entrapment

Under a legal entrapment defense, an individual may not be convicted of a criminal offense if encouraged by the government to do so in certain circumstances (Dillof 2003). Criminal defense attorneys utilize this type of defense often during narcotics cases. The fact-finder must determine and conclude that absent the aforementioned encouragement by government intervention, the defendant would not have committed the criminal act (Allen 1999). As a general rule in legal proceedings, this defense is unavailable if the actor created any conditions that established self-imposed culpability (Robinson 1985).

Forensic Negligence

One of the most significant forensic science scandals occurred at the Houston Police Department Crime Laboratory in 2002. After a formation of an investigative team, forensic analyses reviewed 3500 past cases conducted by scientists at that agency. The investigation culminated in a report detailing numerous, negligent errors committed by staff, even in death penalty cases (Bromwich 2007). State-level oversight likely could have prevented this scandal, at least not allowing it to deteriorating to such a vast level (Goldstein 2011).

Fingerprinting forensic science is not immune to false positive either. Fundamental decisions made by fingerprint experts are prone to contextual influences, leading to errors (Dror et al. 2006). Independent objectivity in the processing and evaluation of information are limited due to cognitive flaws (Dror et al. 2005).

Causal Effect of Investigative Negligence: Failure to Train

The United States Supreme Court case Canton v. Harris (1989) held that the failure to train police officers or investigators exposes police departments to organizational liability, under Title 42 United States Code Section 1983. Deficient training rises to a liable level when a petitioner confirms to the Court that the failure to train by the police department amounts to "deliberate indifference." This concept means that the training deficiencies were negligent enough to significantly raise the level of risk to others they may come into contact with (Ross 2000). Deliberate indifference, as stated in Farmer v. Brennan (1994), consists of a pattern amid "mere negligence and something less than acts or omissions for the very purpose of causing harm or with knowledge that harm will result (Vaughn et al. 2001)." The Court must decide when that balance tips towards indefensible negligence. The two most common forms of claims of this form against police administrators usually fall under allegation of failing to train and failing to supervise (Kappeler 1997; Barrineau 1994).

Protection from Investigation Negligence: The Exclusionary Rule

Before discussing the exclusionary rule, there exists an importance to understand the concept of "evidence laundering (Levine et al. 2016)." This action occurs when officers or investigators make Constitutional mistakes while gathering evidence. Ultimately, that same evidence is transferred to others in their respective agencies, then to prosecutors to make a case. The original mistake, the exposure of which should taint the rest of the evidence in a criminal case, remains hidden. If that evidence is not only negligently gathered but also passed along to a second officer, negligence presents at both the investigator and supervisory levels. The holding in US v. Leon allows for "good faith" exceptions to the exclusionary rule, where criminal evidence illegally obtained would otherwise subjected to suppression. This decision essentially allows for investigative negligence to occur in some respects, unless the negligence rises to the "deliberate indifference" level. Concern arises, however, when there is no knowledge of the original violation. The Courts determined that outlawing single, illegal acts does not deter police conduct. Eliminating the systemic disregarding of Constitutional standards is the objective of the exclusionary rule (Herring v. U.S.). This approach appears to repudiate negligence as a primary factor that would trigger the exclusionary rule, asunder the assumption that reckless behavior can be deterred more readily (Bradley 2012). Courts mandate that prosecutors turn overall items of evidentiary value to the defense, even those that undermine the State's case (Brady v. Maryland; Jones 2010). The problem is awareness of that evidence must exist to the Court in the first place.

The Price of Investigative Negligence: Wrongful Convictions

The price to government officials for investigative negligence is the loss of a conviction and possibly professional embarrassment. The price for defendants is unconstitutional loss of freedom. In 1989, four youths were arrested for the brutal sexual assault and beating of a jogger in New York City's Central Park. The boys all asserted their innocence (Bickel 2002) yet were convicted after a trial and sentenced to prison. An individual identified as Matias Reyes later admitted to the crime, exonerating the defendants (Russano 2004). Nobles and Schiff (2000) contend that operational negligence in policing is routine and are skeptical of the potential that there are authentic reforms in place. The striving of investigators and prosecutors to build the case against an identified accused party tends to increase the acceptance of errors and negligence (Huff et al. 1996). Scheck et al. (2001) reviewed 74 cases of individuals who were freed from prison, due to the efforts by The Innocence Project, an organization that utilizes DNA analysis to exonerate the wrongfully convicted. Some of the more prominent reasons causing the eventual miscarriages of justice included: mistaken identification (82%), police misconduct (50%), trial misconduct (45%), defective forensic science poor defense lawyers (32%), false confessions (witness testimony (20%). The University of California-Irvine and the University of Michigan Law School together formed an organization titled the National Registry of Exonerations (www.law.umich.edu). Compiled statistics for the year 2018 were as follows: There were 151 exonerations. 68 individuals were exonerated of homicide, 17 for sexual crimes, 16 for violent crimes, and 47 for nonviolent crimes. Official misconduct by police officials was the primary characteristic in 107 of the cases, including 54 of the homicide case (79%) exonerations. The state with the most exoneration was Illinois with 49 of the cases, with the next state being New York with 16, demonstrating a prevalent culture of police negligence. Prisoners lost a combined 20,000 years of freedom to false imprisonment. Eighteen years spanned the two studies, and wrongful convictions continue to occur in high numbers, indicating that not enough reform occurred in that time.

Conclusion

Whether an officer on street patrol or an investigator working homicide case, the propensity for negligence is always present. As we have seen in this literature, even if there are competent supervisors capable of recognizing and correcting negligent errors, the possibility remains that they are sometimes not aware in the first place to act. Police officers have a vast amount of discretion while performing their duties during investigations. Without a credible checks and balances system implemented as the norm, human error may persist undetected. As a result, violations of citizens' Constitutional rights will likely continue. As the efforts of the Innocence Project continue to prove, innocent defendants will also continue to be sent to prison for crimes they did not commit. A secondary issue emerges in the courts, where a "minor" act of negligence is not necessarily considered enough to suppress evidence unless it rises to a level of "deliberate indifference." The "good faith" exception to the exclusionary rule, as legal scholars in this chapter indicated, appears to carve out rationalization for negligence. While it is unknown whether the Court will revisit this issue in the future is uncertain. What is certain is the likelihood that human fallibility will continue to produce negligent errors during investigations. While society does not purport to tolerate negligence in the criminal justice system, there also does not seem to be a strategy in place to stem future occurrences. The Innocence Project has made great strides in exposing negligence and exonerating the innocent, yet DNA analysis is not immune to human negligence anymore than fingerprint analysis. More extensive training for investigative supervisors could inhibit the prevalence of occurrences, along with more stringent legal inquiries regarding criminal evidence.

Definition

OSHA – With the Occupational Safety and Health Act of 1970, Congress created the Occupational Safety and Health Administration (OSHA) to ensure safe and healthful working conditions for working men and women by setting and enforcing standards and by providing training, outreach, education, and assistance (OSHA-About n.d.).

Introduction

In 1970, the US Congress passed the Occupational Safety and Health Act (OSH Act). Subsequently, following the passage of Public Law 91-596 in April 1971, the Occupational Safety and Health Administration was established within the federal Department of Labor (DOL). Commonly called The OSHA Act, this legislation was signed into law by President Richard Nixon. The Act was created to establish uniform governmental safety and health standards and regulations to achieve two primary congressional purposes: (1) protect American workers from safety and health hazards in their work environments and (2) protect employers from the burden of costs associated with workplace injuries and illnesses while protecting interstate commerce and production. OSHA did not develop all new standards and regulations for safety and health unilaterally, but rather, adopted by reference many existing industry-specific regulations, such as those found within National Electric Code (NEC), American Congress of Industrial Hygienist (ACGIH), National Fire Protection Association (NFPA), and the Compressed Gas Association (CGA), and codified them within title 29 of the Code of Federal Regulations (CFR). The Act mandates that companies have a "responsibility or duty" to retain a work environment without identified hazards. The Act also tasked OSHA specifically with 13 targeted objectives to ensure both voluntary and involuntary employer compliance with standards and regulations set by the US Congress. According to OSHA's website, www.OSHA.gov, these objectives include:

(1) Encouraging employers and employees in their efforts to reduce the number of occupational safety and health hazards at their places of employment, and to stimulate employers and employees to institute new and to perfect existing programs for providing safe and healthful working conditions;
(2) Ensuring that employers and employees have separate but dependent responsibilities and rights with respect to achieving safe and healthy working conditions;
(3) Authorizing the Secretary of Labor to set mandatory occupational safety and health standards applicable to businesses affecting interstate commerce, and by creating an Occupational Safety and Health Review Commission for carrying out adjudicatory functions under the Act;
(4) Building upon advances already made through employer and employee initiative for providing safe and healthful working conditions;
(5) Providing for research in the field of occupational safety and health, including the psychological factors involved, and by developing innovative methods, techniques, and approaches for dealing with occupational safety and health problems;
(6) Exploring ways to discover latent diseases, establishing causal connections between diseases and work in environmental conditions, and conducting other research relating to health problems, in recognition of the fact that occupational health standards present challenges often different from those involved in occupational safety;
(7) Providing medical criteria, which will assure insofar as practicable that no employee will suffer diminished health, functional capacity, or life expectancy as a result of his work experience;
(8) Providing for training programs to increase the number and competence of personnel engaged in the field of occupational safety and health, affecting the OSH Act since its passage in 1970 through January 1, 2004.
(9) Providing for the development and promulgation of occupational safety and health standards;
(10) Providing an effective enforcement program which shall include a prohibition against giving advance notice of any inspection and sanctions for any individual violating this prohibition;
(11) Encouraging the States to assume the fullest responsibility for the administration and enforcement of their occupational safety and health laws by providing grants to the States to assist in identifying their needs and responsibilities in the area of occupational safety and health, to develop plans in accordance with the provisions of this Act, to improve the administration and enforcement of State occupational safety and health laws, and to conduct experimental and demonstration projects in connection therewith;
(12) Providing for appropriate reporting procedures with respect to occupational safety and health, which will help achieve the objectives of this Act and accurately describe the nature of the occupational safety and health problem;

I

(13) and lastly, encouraging joint labor-management efforts to reduce injuries and disease arising out of employment. (www.OSHA.gov 2019)

Upon the creation of the OSHA Act, the US Congress recognized a need for a special provision within the Act that is called the *General Duty Clause.* The General Duty Clause is *also* commonly referred to as a *5(a)(1). It* is a "catch-all" designed for OSHA to address workplace safety and health deficiencies or unregulated hazards where no legislation exists to ensure organizational compliance for worker safety. The General Duty Clause places the onus on employers to keep the work environment free of known workplace hazards in the absence of an OSHA regulation. Understanding the reciprocal relationship between employer identification of workplace hazards and employee compliance with employer safety measures, OSHA crafted the *5(b)* legislation under the OSHA Act. OSHA *5(b)* was designed for employee compliance with documented employer workplace standards and countermeasures to ensure the worker's safety and health in the workplace. The Act authorized OSHA to promulgate and enforce safety and health standards through the OSHA Division of Compliance offices throughout the USA. The Act also authorized OSHA to provide free voluntary compliance through education and training measures by the OSHA Division of Education and Training Division. Since 1971, the first enactment of the OSHA Act, safety, and health laws have been passed and regulations issued dedicated to industrial hygiene health hazards and workplace safety (Plog and Quinlan 2012).

What OSHA Does

Workplace injuries and illnesses are expensive to organizations. OSHA plays a vital role in protecting interstate commerce by ensuring the workplace safety and health of employees by holding employers responsible and accountable. Primarily, OSHA accomplishes these objectives by identifying known hazards and encouraging employers to recognize likely safety and health dangers in the workplace, quantifying associated risks, and ensuring that employees are given appropriate equipment and training to combat hazards, whether chemical, physical, ergonomic, or biological. OSHA's organizational efforts are two-fold. OSHA Division of Compliance and compliance safety and health officers (CSHOs) enforce current safety and health regulations through programmed and planned inspections of organizations that may result in fines and penalties due to violations. OSHA Division of Education and Training safety and health personnel provide *voluntary* compliance opportunities, called *surveys or technical assistance* (TAs) for private and public companies, as well as state and local government entities with no fines or penalties under normal conditions. *Voluntary surveys* or TAs requested by an employer do not typically result in fines or penalties if violations found are abated but does offer the company an opportunity to proactively partner with OSHA to prevent workplace incidents resulting in injuries and illnesses. Inevitably, OSHA's role in protecting workers remains the same. However, with emerging technologies and manufacturing strategies come new workplace safety and health hazards and associated risks. OSHA strives to stay ahead of these advancements by establishing new and updated guidelines so that workers in these industries are safe in the workplace (Plog and Quinlan 2012).

OSHA regulations are concentrated in four areas: general industry, construction, maritime, and agriculture. Regulations and guidelines differ among the industries due to the variety of workplace hazards (OSHA n.d.).

General Industry

Codified under US law, 29 CFR 1910 general industry standards set forth governmental regulations designed for those industries not included in agriculture, construction, or maritime. OSHA's general industry standards, directives, and standard interpretations are used to regulate general industry companies, such as hospitals, fire departments, mortician offices and funeral parlors, and foundries.

Construction

Codified under US law, 29 CFR 1926 construction regulations set forth regulations designed for industries involved in construction or construction activities. OSHA's construction standards, directives, and standard interpretations regulate construction industries and general industry activities which fall under construction, such as general and subcontractors.

Maritime

Codified under US law, 29 CFR 1915, 1917, 1918, and 1919, maritime regulations set forth regulations for industries involved in maritime or longshore activities. OSHA maritime standards, directives, and interpretations regulate maritime industries, such as long shoring.

Agriculture

Codified under US law, 29 CFR 1928, agriculture regulations set forth regulations for industries involved in agriculture activities. OSHA agriculture standards, directives, and interpretations regulate agriculture industries.

How OSHA Has Helped

Before the OSHA Act, there were no consensus governmental regulations designed for the protection of workers from occupational safety and health hazards. A direct result of the lack of consensus governmental safety and health regulations, the number of workplace fatalities, injuries, and illnesses numbered in the thousands annually, with many workers suffering fatal injuries daily and acquiring long-lasting chronic illnesses. For nearly 50 years, OSHA has worked tirelessly to improve the working conditions for workers in many industries by making them safer and holding both employers and employees accountable. According to the National Safety Council (NSC), for example, since OSHA has become law, the death rate from work-related injuries has been reduced to four per 100,000, or less than one-third the rate of the previous 50 years. In addition, due to OSHA efforts, US companies have become more competitive in a global economy due to a greater awareness of the cost-effectiveness gained from the prevention of work-related injuries and illnesses.

How OSHA Is Going to Help

Due to its mission statement and 13 core targeted objectives determined by the US Congress, OSHA will play an important role in shaping the future of workplace safety and interstate commerce. As advancements in technology in production, service, and quality move forward, new hazards undoubtedly are going to be introduced into the modern workplace that will place workers at risk. OSHA, industries, and companies will have to work together, forging a partnership in continuing to provide safe workplaces, free from recognized hazards. Industries, with the completion of injuries and illness records (OSHA recordkeeping logs), will assist in identifying emerging injury and illness trends, and will also influence OSHA Compliance targeting.

OSHA Jurisdictions

OSHA, a federal program administered through the Department of Labor (DOL), has jurisdiction throughout the USA and its territories. OSHA standards and regulations cover the most private sector, state, and local governmental employers. For example, all USA island territories, including Puerto Rico, Guam, and the Virgin Islands, are covered under OSHA standards and regulations. Although OSHA is a federal program, the US Congress recognized the need for some states to administer their own OSHA program. These *state-plan states* are federally approved OSHA workplace safety programs that are managed by the individual state or territory. A state-plan OSHA program is monitored by federal OSHA and must be as effective in protecting worker's safety and health in the prevention of workplace fatalities, injuries, and illnesses. The number of federal and state-plan OSHA programs are nearly evenly split among the states and US territories.

Federal Level

There are currently 28 federal operated OSHA programs in the USA and its territories. These programs are located in the following states and territories: MT, ID, ND, SD, NE, CO, KS, OK, MO, AR, TX, LA, MS, AL, GA, FL, WV, OH, PA, WI, DE, DC, RI, MA, NH, and the AS MP and GU territories.

State Level

Currently, there are 22 states with their own OSHA programs plus six states that cover only state and local government workers. These 28 states and territories include WA, OR, NV, CA, UT, AZ, NM, WY, MN, IA, MI, IN, KY, TN, SC, VA, MD, IL, NJ, CN, HI, NC, NY, VT, MN, and the US VI and PR territories.

How the General Duty Clause Is Used

As mentioned in the introduction, the *General Duty Clause* of the OSHA Act imposes on employers a "general duty" to provide a workplace free of "recognized hazards" (Morey 1973). OSHA Division of Compliance can cite a company under the General Duty Clause if an existing deadly or dangerous hazard is not mitigated in the workplace. The General Duty Clause is only used in instances where there is not an OSHA regulation to address a specific hazard. The OSHA Compliance officer, when determining if the General Duty clause applies to an organization, is able to prove the violation when the following four conditions exist:

- Workplace has not been free of hazards that endangered workers.
- Workers and others in the company understood that the hazard existed.
- Hazard danger was or is liable to be deadly or produce severe physical harm.
- A reasonable strategy was available to amend the hazard.

All four of these conditions must be answered in the affirmative in order for a violation of the General Duty Clause to be present.

Conclusion

Signed into law by President Richard Nixon, the passage of the OSH Act by the US Congress promulgated the establishment of OSHA. The mission and task of OSHA is to assure that workplace conditions for both men and women are safe and reliable and that workplace safety regulations are enforced. This is accomplished through training, support, and informational assistance. The OSHA Act was deemed necessary because workplace injuries and illnesses were costly to employers, interfered with interstate commerce, and due to public outcry. The OSHA Act specifically gave OSHA 13 objectives to complete, which include the collection of injury and illness data, providing education and training activities to the general public, developing legislation to provide workers with protection from workplace hazards, and others. OSHA has been very successful in reducing the frequency and severity of workplace injuries, illnesses, and fatalities over its 40 plus years in existence. OSHA adopted many safety and health regulations for the protection of workers. However, the US Congress understood due to emerging technologies in production and manufacturing development knew they could not keep pace with promulgating legislation for the safety and health protection of workers. The General Duty Clause, 5(a)(1), was developed as one of the provisions designed for companies and top leadership to be responsible for the protection of their workers despite the presence or absence of regulatory legislation by OSHA. The General Duty Clause is, therefore, a "catch all" legislative device used by OSHA Compliance to cite companies that expose workers to workplace hazards where no legislation exists.

Investigations: Polygraph Use

Frank Chen
John Jay College of Criminal Justice,
New York, NY, USA

Keywords
Deception · Lie detection · Polygraph

Definition

The polygraph measures blood volume, breathing, pulse, and sweat rate of examinees to guide the polygraphist in determining truth and deception.

Introduction

Since the inception of deception detection, physiological stress was always a problematic measurement. Heightened stress responses are often misinterpreted as deception because there is not a single distinctive stress response for deception. Unless this distinctive stress response exists or is identified, no machine would be able to detect lies, specifically the polygraph. When guided by the polygraph, the only capable lie detectors are the prepared polygraphists who carefully study their examinee's physiological responses to control and relevant questions and attempts to beat the machine.

A Brief History on Truth and Deception

Deception started before our first language as humans and played a critical role in the personal gain and survival of many species. For example, anglerfishes use a shiny lure in the shape of a tasty juicy worm above their heads to attract other fish while hunting in the dark sea. Hognose snakes feign death and secrete a foul odor to warn predators that consumption of itself may lead to dangerous diseases, illnesses, or death (Owen 2015). Each example illustrates a different purpose of deception, with the anglerfish's. method attracting others while the hognose snake's method deterring others. We also use deception to attract or deter others, as we can also hang shiny tasty lures above our heads to attract others or secrete foul odors when threatened but that would probably produce mixed results. Regardless of our deception methods, we lie, trick, and deceive others out of fear, personal gain, or habit. "The ability to mislead or deceive probably carried an evolutionary advantage just as did fleetness of foot or the possession of an opposable thumb" (Lykken 1998). Since the birth of this evolutionary advantage, it is very likely that deception detection followed shortly afterward.

Before the recognized importance of deception detection, there was a magical and, at times, a religious belief that the honest would always emerge victorious and the deceptive would

always be defeated. This belief existed in trails by combat, where the honest fighter was blessed based on their truthful character by a higher power and the deceptive fighter would be cursed, weakening them in combat and setting them up for defeat. The honest would also survive in trials by ordeal, such as walking on fire or dipping their arms in boiling water. The assumption was that under these trials, only the deceptive are punished and the truthful are protected (NTLS 2015).

The search for truth started as early as 300 B.C., where Bedouins of Arabia developed a hot metal spoon method where suspects of a crime were required to lick a hot metal spoon three times to determine if they were truthful or deceptive. This ritual was known as the "Bisha," and the assumption behind this truth test was for persons who were deceptive would have a dry tongue and after licking the hot metal spoon would then have a burnt tongue. If the person was honest, their tongue would be moist and not dry, which would protect them from the hot spoon. Accused persons with a burnt tongue after this ritual would be found deceptive and guilty for the crime accused (NTLS 2015).

This salivary physiological response was common in other cultures as well and was also used in China, except the accused were required to chew rice instead of licking hot metal spoons. When the accused chewed and spat out the rice, rice that stayed on the accused's tongue indicated deception. The assumption was that if the accused was innocent, their tongue would be wet and not dry because there was no reason to stress over the test if they were truthful (Leafloor 2014). Similarly, when we are under situations of high stress or deception today, one of our immediate physiological reactions is the dryness of throat, causing us to swallow as a response. Other physiological responses include increased breathing, pulse rate, and sweat, which of course led to other deception detection techniques.

African tribes used a smelling technique, where the accused stand around an African medicine man in a circle. The medicine man continuously smells the necks of the accused while delivering "blood-curdling" shouts along with another feverish smell of the accused (Trovillo 1939). These shouts heighten the stress levels of the accused, making them sweat uncontrollably and excessively. In this deception detection technique, it uses perspiration as the deception physiological response, and thus the person who sweats the most must be deceptive.

As you probably guessed, the aforementioned methods were not very reliable and often led to innocents punished for crimes they did not commit. Thankfully, modern-day deception detection techniques advanced beyond the use of hot spoons, rice, or a strong sense of smell. They start with nonverbal indicators, unique to each individual's character and can range from rubbing or scratching the nose, eyes, ears, or the back of the head. Other indicators include grooming, heavy breathing, or cracking fingers. These nonverbal gestures are unique because they are learned through associations with others and start as early as childhood. However, these nonverbal indicators are not signs of deception; they are only signs of stress and are often misinterpreted as deception, similar to the techniques identified earlier. The distinction between stress and deception is assumed through our human behavior analysis skill, which is challenging to measure and accurately document. For starters, determining truth and deception depends on your own truthful or deceptive personal character and requires you to be well aware of your physiological stress responses. If you are truthful most of the time, you should search for truthful cues and if you are deceptive most of the time, you should search for deceptive cues. You can also be a truthful person and search for deception cues and vice versa but that might require extra practice. It might be easier for some of us to interpret verbal, nonverbal, and written forms of communication with the truthful or deceptive character and cues they are most familiar with – themselves or an intimate other. The act of measuring stress to assume deception is the function of the Lie Detector machine, also known as the polygraph.

The Genesis of Lie Detection Machines

The first prototype of the modern-day polygraph started with the analysis of blood flow within

a deceptive person. In 1730, Daniel Defoe's essay on prevention of street crime wrote how "Guilt carries fear always about with it; there is tremor in the blood of the thief" (Grubin and Madsen 2005). Defoe determined how unequal pulse changes and heart palpitations are strong indicators for deception during questioning which started in the early twentieth century with Austrian Benussi. Benussi's research identified the relationship between blood pressure, pulse, and breathing rate now known as the Benussi ratio. Using the Benussi ratio, William Marston's systolic blood pressure deception test became the prototype for the modern-day polygraph. Marston's polygraph prototype used a standard blood pressure cuff and stethoscope while assuming the relationship between specific lie responses and changes in systolic blood pressure.

Marston's prototype polygraph was submitted as evidence in the Supreme Court case Frye v. United States, 1923. Accused of robbery and murder, James Frye took Marston's lie detector test and passed, which assumed Frye to be innocent. The trial judge refused to allow the admissibility of Marston's apparatus as scientific evidence based on questionable validity from the scientific community and is now known as the Frye standard test. Since the use of Marston's lie detection device in Frye v. United States, it attracted the attention of other professionals and eventually became the modern-day polygraph.

Larson created the first modern polygraph apparatus in 1921 that transcribed the physiological responses of blood pressure, pulse rate, and respiration (hence the name polygraph which means many writings). This first model of the polygraph proved successful and was later advanced to be portable by Leonarde Keeler, Larson's disciple. Keeler furthered the portable polygraph and improved it to measure pulse rate, blood volume change, breathing, and sweat in 1939. Keeler's model of the polygraph was the first lie detection instrument purchased by the Federal Bureau of Investigation and became the first prototype for the modern-day polygraph. Since the creation of the polygraph, professionals who were heavily involved in determining truth and deception merited its utility.

Polygraph Function

The polygraph records physiological responses of an examinee under stress. Under high levels of stress, which causes physiological responses to become more apparent, the sympathetic nervous system kicks in. The sympathetic nervous system is one of the two parts of our central nervous system and activates when we sense danger (also known as Walter Cannon's fight/flight response) (Brown and Fee 2002). Over the years, Bradford's fight/flight response was widely referenced and is now sometimes referred as "the four Fs" (fight, flight, freeze, and our popular and offensive four-letter word starting with an F and ending with a K). While experiencing one of the four Fs, the polygraphist determines truth and deception through interpreting polygraph charts and nonverbal behaviors during sympathetic stress. Some example of nonverbal behaviors include and are not limited to (a) pupil dilatation; (b) inhibition of salivary glands, waste elimination, and gastrointestinal tract; and (c) increased activity in breathing, sweat glands, and heart rates. These nonverbal behaviors could be deception indicators – some of which include "gaze aversion, increased or decreased movement, longer and more frequent pauses, a slower speech rate, hesitations, and speech errors" (Grubin and Madsen 2005). These categories of nonverbal behaviors are indicators of deception unique to each individual, thus requiring the polygraphist to study and determine baseline behaviors prior to assuming stress responses as deception.

So how does the polygraph measure physiological stress to assume deception? The modern-day polygraph measures breathing, heart rate, blood volume, and sweat with "(1) two expendable bands positioned around the thorax and the abdomen, measuring respiration, (2) two electrodes attached to the inside of the hand, measuring electrodermal activity, and (3) an inflatable cuff positioned around the upper arm registering blood pressure" (Meijer and Verschuere 2010). According to Bruno Verschuere, "skin conductance response is the most frequently applied and best validated measure for the detection of concealed information" (2010). Other scholars

argue that breathing, heart rate, or blood volume to be stronger indicators of deception. Since there is no unique pattern or physiological response that would determine truth and deception, the polygraph is simply an instrument that records the physiological responses to guide a polygraphist in determining truth and deception.

Physiological readings are always accurate, but the challenge is proper interpretation of the readings (Aftergood 2000). The Supreme Court Case United States v. Scheffer in 1998 stated that "there is simply no way to know in a particular case whether a polygraph examiner's conclusion is accurate, because certain doubts and uncertainties plague even the best polygraph exams." According to Lykken, "We have already noted that for there to be an instrument that literally detects lying, there must be a specific lie response, a distinctive involuntary, bodily reaction that everyone produces when lying but never when telling the truth. There will never be a Truth Verifier (lie detector) until a specific lie response can be identified" (Lykken 1998). In short, since there is no specific lie response, no instrument will be able to detect lies.

Therefore, since the creation of the polygraph, there was an acknowledgment on how the polygraph is not a lie detector machine. There was also the growing concern that the polygraphist will be subject to bias and is not immune to uncontrollable factors that may alter their discretion in determining truth and deception. Nevertheless, the polygraph is still termed as the "lie detector test" with many researchers challenging the validity of its capabilities in determining truth and deception. The truth is that the polygraph does not determine truth and deception; it is the polygraphist conducting the exam with the aid of the polygraph and through the proper use and delivery of interview questions.

Phases of the Polygraph Exam

The polygraph exam is only successful if the polygraphist properly delivers each phase. Prior to the first phase (pretest), the examinee must be formally scheduled and given ample time in advance. This will allow truthful examinees to relax and calm down before the exam while heighten the stress of deceptive examinees. The first phase is the pretest interview and cannot be skipped or ignored at all costs. During the pretest interview, the polygraphist will introduce the examinee to the examination room and equipment, obtain informed consent for testing, and familiarize the examinee about the exam process, so there are no surprises throughout the exam. The polygraphist must be transparent and be very clear to the examinee about the process, the machine attachments, and recordings to ensure exam confidence. Lastly, the examinee must feel comfortable in the room, such as not feeling too hot or cold or have a need to use the restroom as any discomfort may distort polygraph chart results. This phase normally should take up to 20–30 min (Reid and Inbau 1977).

The polygraphist will demonstrate how the polygraph works through a mock test, where the examinee is instructed to tell a lie and the examiner will show that the polygraph has caught the lie and provide evidence of its accuracy. The polygraphist in this phase can also determine the examinee's behavior, character, and truthfulness "based on the examinee's demeanor and responses in the pretest interview and during the charting" (National Research Council 2003).

Depending on the type of interview, the polygraphist can also personalize the pretest interview by using psychometric techniques such as graphology, House-Tree-Person test, psychogeometry, the Thematic Apperception Test, and others to determine baseline behavior and establish rapport and theme. These psychometric techniques are not designed to determine truth or deception or to be a substitute to the polygraph. Psychometrics are used at the discretion of the polygraphist, which, if used incorrectly, may negatively affect the outcomes of the polygraph readings and interpretation. The purpose of the pretest interview is also to relieve an innocent examinee's stress while heightening the sympathetic arousal of a guilty person. Therefore, the polygraph not only allows a polygraphist to determine an examinees physiological response and establish rapport but

also indoctrinate the mind-set of the examinee that if they are innocent, they will be deemed innocent and if deceptive, they would be found guilty (Lewis and Cuppari 2009).

The pretest interview can also be an opportunity for the polygraphist to use other rapport-establishing techniques, such as Richard Bandler's Neuro-Linguistic Programming (NLP). NLP has evolved over the years since its inception in the 1970s. The original purpose of NLP was to understand others better through studying eye movement gestures. Bandler categorized our five senses (sight, hear, smell, taste, and touch) into visual, auditory, and kinesthetic (smell, taste, and touch). Based on your eye direction when answering questions (top, middle, or bottom), you were a visual, auditory, or kinesthetic learner. Additionally, looking left or right while looking top, middle, or bottom would indicate truth or deception (Bandler et al. 1979). Regardless of the original intention of NLP, it is now employed as a method to establish theme in communication and in the pretest of the polygraph exam. There are many methods to establish theme, but one of the easiest methods is to determine what type of learner an examinee is and to use the words associated with the learning method. For example, if the polygraphist finds their examinee to be a visual learner, they would use visual-oriented words such as "I see what you mean." If the examinee is an auditory learner, the polygraphist would use auditory-oriented words such as "sounds good." Lastly, if the examinee is a kinesthetic learner, the polygraphist would use kinesthetic words such as "smells fishy" or "feeling salty." This technique as with many other psychoanalysis techniques is a pseudoscience and is not always scientifically proven to work. Regardless, if it actually works or not, these techniques would boost the polygraphist's confidence in determining truth and deception. It is this immeasurable confidence that drives the polygraphist to hold their breath longer than the examinee, to separate and exhaust deceptive examinees from the truthful. In short, this NLP rapport technique is one of the many theme techniques professionals can use to establish rapport and can be used in the pretest phase of the polygraph exam.

In the in-test phase, the polygraphist must communicate every question clearly and carefully as shared in the pretest phase. Polygraph exam questions cannot be ambiguous or use sensitive words related to the crime. For example, in a child molestation case, the polygraphist should not use the word "rape" or "pedophile" but instead use terms such as "inappropriately touch" or "sexual intercourse." The polygraphist should also not use technical jargon that the examinee would not understand such as fellatio, as it would lead to confusion and inaccurate polygraph writings. Questions should also not be lengthy as it would dampen the stress levels of deceptive examinees and stress out honest examinees.

Three important types of questions asked during the in-test phase are control, relevant, and irrelevant. Before the test begins, the polygraphist will read their list of questions to the examinee in any order to ensure they understand each question. This list of questions will have a mix of control, relevant, and irrelevant questions. The sequential order of control, relevant, and irrelevant questions is extremely important and changes based on the type of interview. There are many standardized test orders, some of which also have additional instructions. For example, by assigning two relevant questions one after another and asking the examinee to answer truthfully to one and deceptively to another is known as the positive control test. By asking examinees to deceptively answer every control question is known as the directed lie test. Regardless of the question set, the polygraphist will inform the examinee that only the questions read to them will be asked and that there are no surprise questions. The most well-known polygraph question set is the control question test, which focuses on physiological responses to control and relevant questions.

Control questions are vague questions that cover events from previous life experiences and are recommended to be related to the crime accused. Control questions are meant to make the subject uncomfortable because the questions are designed to make it difficult for the examinee to answer "no." For example, in a crime related to robbery, the examinee would be asked, "in your

entire life, have you ever stole something?" For most of us, we take things from time to time and would not classify the action as stealing. For example "borrowing" scissors or other office supplies from our colleagues and "forgetting" to return it. Although the intention to steal was never there, the action of taking other peoples' possession without permission can be labeled as stealing for some and not for others. For individuals who would label this action as stealing, they would experience physiological stress when confronted with this control question. "Control questions are designed to provide the innocent suspect the opportunity to become more concerned about questions other than the relevant questions and to produce stronger physiological reactions to control questions. If the subject shows stronger physiological reactions to the control as compared to the relevant question, the test outcome is interpreted as truthful. Stronger reactions to the relevant questions indicate deception" (Lykken 1998).

Relevant questions are questions that are directly related to the crime at hand. If the suspect has committed more than one crime, the crime that is the most serious will stress them out the most, providing the strongest physiological response. For example, if the suspect was involved in three different drug-related crimes and one out of the three involved murder, the murder case is most likely going to occupy the suspect's concentration, focus, and effort in concealing deception. The other two drug-related crimes would be the least concern to the suspect and produce lower stress responses. This is known as the anti-dampening concept and is defined by Lykken as "a person's fear, anxieties and apprehensions are channeled toward the situation which holds greatest immediate threat to his self-preservation or general well-being, (and that there is) an ability within us to tune in that which way indicate trouble or danger by having our sense organs and attention set for a particular stimulus and oriented in a manner that will dampen any stimulus of lesser importance" (1998). For example, if a respectful law-abiding student is taking a polygraph exam for a job opportunity in the federal government and were previously engaged in "agriculture," questions related to experimenting with cannabis would heighten the student's responses knowing that it would disqualify them from job employment. Questions related to murder or stealing would not generate strong physiological responses because the student's entire focus is on their past cannabis experiences. In sum, the anti-dampening concept will affect responses to relevant questions depending on the situation, examinee's concentration, and focus.

Irrelevant questions are questions that are completely irrelevant to the crime under investigation. Sample irrelevant questions are "Is your name Phil?", "Did you ever ride a bike?", and "Are you in New York right now?" "The primary purpose of the irrelevant questions is to ascertain the subject's normal reactions – his 'norm' – under test conditions" (Reid and Inbau 1977). The normal reactions are important because it is also the examinee's baseline behavior. Although irrelevant questions help the polygraphist establish the norm behavior of their examinee, the problem is that if the examinee lies on the irrelevant questions and they are not confronted on the lie, the examinee will believe they can evade detection when confronted with relevant questions. As stated earlier, depending on which set of questions produces higher levels of physiological response, the subject will be deemed truthful or deceptive. If the subject shows higher physiological responses to the control questions, they are deemed truthful. If the subject shows higher physiological responses to the relevant questions, they are deemed deceptive. The actions taken by the examinee to alter their physiological responses to control and relevant questions to misguide the polygraphist is known as "beat the machine."

Beat the Machine

"Beat the machine" is defined as the examinee's attempt to manipulate the results of polygraph readings through hidden methods undisclosed to the polygraphist. An estimate of 20% of examinees often try to "beat the machine" through

various methods such as voluntary muscular movements to mislead the polygraphist during questioning (Reid 1945). These muscle contractions are also known as peripheral resistance, where based on muscular activity, the resistance of blood flow increases or decreases. Reid's research shows that these voluntary unobserved muscular movements have the following properties: (a) all typical blood pressure responses can be produced voluntarily and at will, (b) voluntary and at-will blood pressure responses can be differentiated from true indications of guilt, and (c) recorded evidence of muscular evidence is an indicator of deception (1945). In short, unobserved muscular movements during polygraph tests are methods to beat the machine, specifically when asked control questions.

The best advice to beat the machine is to identify the control questions and to alter your physiological reaction to the control questions. This action will make it difficult for the polygraphist to differentiate between control and relevant question physiological responses. A method to alter your physiological reaction is through self-inflicted pain or tightening your muscles to control physiological responses. If you are unsure of how to identify the control questions to beat the machine, you can also relax, hold your breath, or do anything to calm yourself when you are asked the relevant questions. Any method that would cause the polygraph charts to show similar physiological responses to control and relevant questions will allow you to beat the machine successfully. Being mindful of methods to beat the machine will help subjects pass the polygraph test, as "a high proportion of honest people will fail lie detector or honesty tests when they rely on their truthful answers to demonstrate their innocence or good character. Meanwhile, the more clever of the villains will employ countermeasures to ensure that they manage to pass" (Lykken 1998).

After the in-test phase is the posttest phase, where the polygraphist will have the results of the exam immediately after the in-test phase. The polygraphist will determine the examinee as deceptive, honest, or inconclusive. Deceptive is determined by the examinee showing consistent and stronger physiological responses to relevant questions. Honest is determined by the examinee showing consistent and stronger responses to control questions. Inconclusive is when the polygraphist is unable to determine if the examinee is deceptive or honest. Deceptive and honest exam results are determined by a numerical scoring system, traditionally scoring deceptive responses as negative points and honest responses as positive points (Synnott et al. 2015).

Measuring Polygraph Validity

Measuring polygraph validity is extremely challenging and if not, more confusing and complicated given the required learning curve of accurately interpreting and transcribing polygraph charts during testing. Although assumingly used for determining truth and deception, the polygraph is only an instrument that would guide the polygraphist in reassuring their discretion. Empirical studies show that "in experimental settings, the ability of the average person to catch a liar is rarely above 60%" (Grubin and Madsen 2005). Additionally, the United States Justice Paul Stevens determined the polygraph only having an 85% to 90% accuracy reliability rate with critics estimating a 70% accuracy rate (Gershman 1998). Given the percentages here, it appears that the lie detection rate between an average person and the use of a polygraph can be up to 25% when using the polygraph. Do not let these percentages fool you, as "the clinical judgment of a polygraph examiner is no more valid than that of any other observer, just as subject to bias and prejudice, and probably wrong nearly 50% of the time" (Lykken 1998). Empirical research on lie detector accuracy rates and its percentages are best explained by Benjamin Disraeli's quote "There are three kinds of lies; lies, damn lies, and statistics."

Testing Polygraph in Laboratories

Critics who attempt to debunk the validity of the polygraph often test its legitimacy through controlled laboratory settings. Laboratory experiments on measuring polygraph validity often

produce misleading results given the nature of the experiment. Laboratory settings offer a completely different environment and experience to examinees compared to real-life polygraph exams. "Laboratory studies that are based on non-emotional orienting responses absolutely fail to replicate the field conditions that elicit emotional defensive responses wherein both the guilty and innocent examinee's primary emotion is 'fear' of the consequences if found deceptive which in criminal cases could result in imprisonment" (Matte 2011).

Other polygraphists drew the same conclusions regarding polygraph laboratory studies. Lykken believed that laboratory studies "have serious disadvantages for predicting lie detector accuracy in real-life criminal investigations" (Lykken 1998). The first disadvantage is that volunteers do not accurately represent criminals in real life and, thus, will not express or experience real concerns to the lies they are instructed to tell. The second disadvantage is that there are no perceivable consequences for volunteers if they fail the polygraph exam. The third disadvantage is that laboratory polygraph mock studies occur shortly after a mock crime occurs. This does not happen in the real world, where polygraph testing may occur days or even weeks after a crime occurs. Therefore, we can conclude that laboratory tests cannot determine polygraph validity.

Employee Polygraph Protection Act of 1988

According to The Employee Polygraph Protection Act of 1988, all private employees are protected from an employee requirement to take the polygraph exam. Employers cannot request or even suggest employee candidates to take the polygraph exam, nor are they allowed to terminate an existing employee because of a refusal to take a polygraph exam. The Employee Polygraph Protection Act of 1988 does not apply to federal, state, or local government agencies, nor does it apply to professions regarding national defense.

Currently, the polygraph is used to screen applicants for government positions and is known as the applicant screening test. The polygraphist follows the same process as they would normally and work off multiple question lists. The examinee is tested to see if their physiological responses remain constant across all content areas, from drugs to violence to stealing and other acts that would disqualify them for employment. Any content area that draws stronger physiological responses will be asked repeatedly with longer pauses to determine deception. If the polygraphist is convinced the examinee is deceptive, they can stop the polygraph and directly confront them about their deception. If the examinee continues to deny deception, the polygraphist will continue with the test and return to the sensitive content area later. As you probably guessed, many examinees also try to beat the machine. The most important fact to remember in preparation for the polygraph exam is your belief in the machine. "Once you believe in the machine, it works. Once you believe in the charts, it works. The polygraph does not believe in you, but you will believe the polygraph" (Lykken 1998).

Conclusion

Although known as the lie detector machine, the polygraph would only serve as a guide for the polygraphist to determine truth and deception as a Microsoft PowerPoint presentation would serve as a guide for a presenter. It is not the flashy graphics or song cues in a PowerPoint presentation file that makes the presentation or lecture a living masterpiece – it is the presenter himself or herself. As for the polygraph, it is not its physiology measurement capabilities, it is the polygraphist himself or herself. The polygraph only appears to be the better lie detector because of its scientific presence and physiology recording function. When we combine the polygraph presence with our naïve dependency on technology, we believe in the machine. It is true about the polygraph that it is close to perfect in measuring physiological response, but it still requires a person to use their discretion to determine truth and deception given the unique character and nature of each individual person.

[2]King Edward Medical University, Lahore, Punjab, Pakistan

Keywords

Crime · Crime reconstruction · DNA evidence · Forensic medicine · Rape · Sexual abuse · Sexual assault · Sexual violence · Violence against women

Definition

Legal, sociopolitical, clinical, and moral definitions differ significantly, but generally in most jurisdictions, any unwanted sexual attack or attempt which may or may not involve force – such as fondling, grabbing, or verbal threats – is considered a sexual assault, while rape is an aggravated form of sexual assault in which penetration is involved.

Introduction

The investigation of sexual assault differs significantly from other criminal investigations in many ways. Nonreporting and delayed reporting are very common in sexual assault cases. Even the victims who choose to report the crime may not be in a physically and mentally stable condition. False allegations are also a common phenomenon.

On the other hand, physical and forensic evidence needed to prove assault deteriorates quickly with time. Following standard protocols used for investigating other crimes can be a dangerous pitfall in sexual assault cases. This necessitates a great deal of care on the part of the investigator, without compromising time efficiency, to collect evidence, and deal with the victim and alleged perpetrator with utmost care. For investigators who are new to sexual assault investigations, the preconceived notions derived from films, fictions, or hearsay can cloud their judgment and imperil investigations that are often very different in reality.

Investigation of sexual assault is a process by which the investigator determines what happened and can reconstruct the crime scene with suitable explanations derived from the victim, eyewitness, and offender statements and corroborated by physical and forensic evidence. For investigating sexual assault, only criminal violations of a penal code enforceable by the courts are relevant.

The criminal law definitions of sexual assault differ across different jurisdictions. Therefore, investigators should adhere to legal interpretations of the statute in consideration when investigating a sex-related crime (Morgan and Kena 2018; Kruttschnitt et al. 2014).

The elements of sexual assault investigations can be classified into four broad categories: (1) investigative response, (2) victim management, (3) reconstruction and physical evidence, and (4) analyzing offender. These broad categories need to be examined in detail to enable an investigator to probe and prosecute sexual assault cases in an effective manner (Savino and Turvey 2011).

Investigative Response

Sexual assault investigations start with first responders when a crime is reported. The next phase is the preservation of the evidence at the crime scene and its management in a manner that vital elements that can impact investigation and trial are carefully handled. The investigators then begin their investigation by examining the crime scene thoroughly and recording statements of victims and perpetrators, if possible. A cohesive and comprehensive response significantly increases the chances of solving the crime, apprehending the offender, and sustaining a trial.

First Response

Savino and Turvey (2011) argue that the first response by its very nature is a rush to the crime scene, which is often disorganized in any crime. In sex-related crimes, three additional factors are in play, and improper handling can lead to inaction. First, any personal issues of the investigator and the intimate nature of the crime can lead to an uncomfortable environment for the investigator. Second, improper training often results in under documentation because the investigators believe that the emotional nature of the victim may result in a contradictory statement, thereby rendering future prosecution difficult. Third, the improperly trained investigator often under collects the physical evidence for the same fear of contradiction noted above. It is practical to know that Andrew Silke (2001) reviewed Brent Turvey's book, *Criminal Profiling: An Introduction to Behavioral Evidence Analysis*, contending that Turvey uses inductive reasoning at the crime scene. Working backward from a conclusion is not best practices for most investigators, and this criticism of Turvey is not exclusive to Silke. Turvey's investigative process, however, is widely accepted.

The first responsibility of a sex crime investigator is to determine what happened and whether or not what happened constitutes a crime. If so, the detective should proceed to arrest the persons in violation of the law. The investigator should always assume that the case will go to trial and therefore preserve evidence accordingly. There are three critical aspects for the investigator:

(1) interview the officer who filed an initial report or reached the crime scene first, (2) preserve the crime scene, and (3) proceed to a preliminary interview of the victim with witnesses and officers present. The investigator should make a case book of relevant information, tips, and leads.

The investigator should be well versed in the relevant law to understand what evidence needs to be collected and preserved in order to prove a case in the court. The suspects can only be arrested if there is "probable cause" that a crime has been committed or is being committed by the person arrested. This can only be justified in the court with a detail of the facts and circumstances that require an arrest. A mere suspicion does not constitute probable cause (Savino and Turvey 2011). Chisum and Turvey (2011) describe the actions the first responder should complete before the arrival of the investigator. These include making the crime scene safe by securing the crime scene and restricting access to it, rendering aid to the victim, keeping victims, suspects and witnesses separate from each other, and protecting evidence from deterioration. The attitude of the investigator should be helpful and encouraging. A dismissing attitude can easily put off witnesses and victims from seeking help and cooperating with the investigation. The investigator should be aware of the concerned crime lab and forensic help required for the case. Forensic evidence may often make or break the case. Therefore, a good investigator should know the different types of forensic evidence and sciences. This enables effective and efficient coordination with the forensic team sent to the scene. Some crime labs face serious backlogs, and collected DNA evidence may not turn into objective crime data because of non-pursuance by investigators. Lab personnel may only give importance to the case being pursued, thus leaving many rape kits untested (Savino and Turvey 2011).

Preservation and Management of Crime Scene

Crime scene preservation and management is an essential first response consideration for the investigator. Large metropolitan police departments have special squads and teams to deal with different crimes. Of these, sex crime units provide the expertise needed to investigate sex crimes, but very often, a single crime scene may involve multiple units. In cases involving homicide, burglary, and sex crimes, various units need to coordinate. National Forensic Science Technology Center (NFSTC) details various crime scene procedures and protocols that investigators should follow to preserve and protect the crime scene. The document emphasizes establishing leadership and control on the investigation and its media coverage without compromising the crime scene in any manner (NFSTC 2013).

Following the initial receipt of information and persons involved, according to the NFSTC, the involvement of the safety of law enforcement personnel is determined. A scene assessment is then conducted to ascertain site safety issues and search warrant requirements. The investigator should then conduct a "walk-through" of the crime scene if it does not interfere with the evidence. Some crime scenes require immediate documentation and preservation of evidence before a walk-through is done. Note-taking and logging the entry/exit of persons present at the crime scene is essential and very helpful in subsequent identification and prosecution of the suspects. After this initial assessment of the crime scene, the investigator should proceed to constitute a team of personnel who are well trained in the processing of the crime scene. The investigators and scene-processing team should take measures to avoid hazards and cross-contamination in order to preserve the evidence. The processing of the scene requires extensive documentation. The scene should be photographed, and photography should be supported with video of the scene. Sketches and distances of the evidence and important locations should also be carefully documented to avoid any contradiction in the future. If the circumstances demand following a procedure different from the standard protocols, then such circumstances should also be noted and documented at the scene. Sketches should be drawn to scale, if possible.

Next follows the collection of evidence, methodically, and systematically. Prioritization is important. The most "transient evidence" should

be collected first, followed by the least intrusive, and then the most intrusive evidence should come last. A crime scene search is of four types: (1) lane or strip search, (2) grid search, (3) zone search, and (4) spiral search. In lane or strip search, the investigators walk in parallel along predetermined lines or strips in the same direction. If the searchers go perpendicular after completing the lane search, then this is known as grid search. The time taken is doubled. However, the advantage is a more thorough and accurate search. In zone search, the area is divided into adjacent zones, which are then searched separately. The investigators may choose to move in a spiral inward or outward to search, but the outward spiral method can result in loss of evidence when the searcher is moving towards the center initially to search. In cases involving unique evidence items that need handling by trained professionals, the non-expert handlers should wait and allow the appropriate personnel to collect and preserve evidence. Flammable liquids that can burn and destroy the whole crime scene need special handling to avoid damage to people as well as property.

Similarly, bodily fluids such as blood, saliva, and semen, which are essential for DNA profiling, should only be handled by an expert or trained professionals. Bombs, explosives, firearms, ammunition, and voluminous documentation are other areas where subject matter experts can be significant in a safe but efficient evidence collection. Packaging and marking of these types of evidence should also be done by trained staff. Tool mark evidence, for instance, is collected by using castings. *Trace evidence*, the evidence composed of tiny materials found at the crime scene such as hair, pollen, stains, requires specialized equipment for collection, packaging, and storage. Footwear impressions, motor vehicles, and electronic gadgets need different resources to preserve evidence related to the crime (NFSTC 2013; Chisum and Turvey 2011).

Crime scene investigation is the process of using crime scene evidence to establish facts of the case scientifically. The investigator examines the physical evidence, statements of victims, suspects, and witnesses, and then goes beyond the evidence to connect the dots and establish what happened, based on facts. Savino and Turvey (2011, pp. 139–173) mention that the investigation begins with determining the *point of contact*, which is the point where the suspect initially contacted the victim, and which may not be the actual crime scene. The *primary crime scene* is the location or point where the principal criminal activity took place. This is the scene that gives the most physical evidence and is generally the scene where the suspect probably spent the most time during the crime. In the case of multiple crimes, the primary crime scene for sexual assault may be different from other crimes, such as homicide. The scene where the sexual assault did not take place, but where the offender and the victim were present, is a *secondary crime scene*, relevant for the investigation and collection of evidence. The *intermediate crime scene* is the setting between the main crime scene and disposal site where the evidence or victim was dumped or disposed of. The victim and suspect *medicolegal examination*, involving medical and legal aspects, is of prime importance in establishing what acts did or did not take place. They, together with the statements of the victim, suspect, and the witnesses, put the evidence in perspective and help the investigator reconstruct the crime scene. Reconstruction of the crime scene should consider all evidence, statements, and reports in a sophisticated manner, thereby establishing the truth.

Victim and Suspect Interviews

Interviewing victims and suspects of sexual assault is very different from other crimes. Due to the intimate nature of this type of crime and the taboos and stigmas associated with sex-related crimes, combined with the physical violation alleged to have occurred, severe trauma can result in behavior unlikely to be observed in other heinous crimes. Victims need a degree of comfort and time to speak coherently. They may show odd behavior and may not recall all the events chronologically (Dworkin et al. 2017).

The first issue is to gather as much history of the victim as possible. If the victim reported any crimes previously or belongs to a profession or ethnic group more prone to sexual violence, these can be important indicators to extract information

from the preliminary interviews. As mentioned above, preliminary interviews provide basic information that can be a good starting point, but more interviews are needed as the victim becomes more stable, and the investigator collects more evidence to corroborate the statements of the victim. The basic requirement is to establish trust with the victim. The victim may not be forthcoming due to a variety of reasons. The last thing the investigator wants is to convey a notion to the victim that causes a loss of trust in the investigation. If the victim stops cooperating, the easiest of cases can become very difficult to sustain in the court of law (Chisum and Turvey 2011).

The victims may resort to some lying to protect themselves or people close and dear to them. These lies may not be a big problem if the investigator can put things into context. However, any failure on the part of the investigator to know these issues can jeopardize the trial when such things are brought up by the defense and can easily create doubts on the truthfulness of the crime itself. In short, when the victim is truthful in detailing the actual assault, the case remains solid even if there are some inconsistencies in victim statements throughout the investigation (Searles and Berger 2018).

The time factor should be carefully observed by the investigator. Although it is generally better to interview as early as possible, peculiar circumstances of the case may necessitate a delay of 1 or 2 days. The follow-up interviews and documentation of these interactions should be precise and carefully preserved. The audio recordings, if permissible by law, should be preferred over note-taking or written statements. Interviews should be held in private, as the presence of family, or other individuals, may prevent a victim or offender from being forthcoming. Many questions are not a good strategy as they can confuse the interviewee, but asking the same question repeatedly may help get more information. The interviewer should be prepared to listen and let the interviewee talk. More voluntary information is always better than interrupting the interviewee or sticking to an investigative plan too rigidly. Savino and Turvey (2011, pp. 184–85) recommend a Frame-by-Frame Analysis (FFA) technique where the interviewer focus is on one frame or event at a time. At each frame, the questions try to elicit as much information as possible from the interviewee before moving on to the next subject or time frame. FFA is most useful for victim interviews but can also generate useful information in suspect interviews.

FFA helps significantly in establishing the truthfulness of the grievance and obtaining a confession, despite inconsistencies in the statements. Preliminary interviews can serve as a starting point to structure an FFA-style interview by asking for specific details and time. The exact nature of FFA allows examining the body language of the interviewee for a longer time to gauge truthfulness. Interviewing suspects is different in many aspects. Aside from giving the *Miranda Warning*, which informs the suspect of the right to remain silent, the investigator must have a clear plan for the interview. This preparation enables the investigator to concentrate on key elements and obtain pivotal information needed from the suspect. The investigator should always let suspects tell their side of the story. Once suspects begin talking and telling their side of the story, the investigator should engage in a conversation at key points to arrive at the truth. The investigator must be prepared to fail and have an alternate plan but guard against shutting out the suspect. Nonetheless, the investigator should always avoid obtaining a false confession through pressure or intimidation.

Savino and Turvey (2011) further explain that interviewing children in sexual assault cases can be very challenging. The younger the child, the more likely that he or she would feel intimidated by the investigator. Therefore, the investigator must make an effort to reach the level of the child to make him or her comfortable. However, the investigator should avoid an interview in the presence of parents because the children would often not reveal anything substantial in that situation. Parents often begin answering in place of a child, and the child then believes that every question should be directed to the parents. Likely, a child victim has already been threatened by the perpetrator to remain silent. The investigator should first build a rapport with the children enabling them to feel comfortable and then

commence talking about the incident. The investigator should avoid leading questions, compounding trauma, and asking in judgmental terms. Children have short attention spans and can be easily distracted, of which the investigator needs to be aware. Most importantly, children should be asked if the suspect asked them to remain silent as it can help establish criminal intent. Preteen and teenage male victims are the most difficult to interview as they often believe that talking about the sexual act can label them weak or homosexual.

Victim Management

The victim is the most important link in a sexual assault case. Very often, the victim's body provides important evidence about the suspect as well as the nature and severity of the assault. The victim interview has already been discussed in detail. Therefore, in this section, the emphasis is on the aspects of victim management other than the interview. These aspects can be subdivided into four categories: (1) forensic examination of the victim, (2) eyewitnesses and identification, (3) victim trauma, and (4) false allegations.

Forensic Examination of Victim

The victim's bodily injuries may often provoke the emotions of those investigating, but the investigator should not be affected in objectivity by these emotions. The myths regarding rape victims persist in society. For example, the victims are often blamed for the rape. Sex workers are not believed to be truthful, and provocative clothing is often touted as the reason for rape. Some people think that the victim could have avoided the rape but chose not to do so. That the victim did not fight back is also blamed for the incident. The victim-blaming myths also work conversely. Some victims, including those assaulted by intimate partners, are considered "unrapeable" and hence not believed. These myths have been debunked repeatedly but, unfortunately, persist in every society. An investigator should guard against developing these preconceived notions (World Health Organization 2003).

The recommended approach is to investigate each aspect of the victim separately. Personal details of the victim in general and at the time of an assault are an essential starting point. Physical characteristics and what the victim was wearing or carrying at the time of assault should be recorded diligently. The digital evidence from phones, laptops, and web surfing activities should also be gathered. Victim items and residence should be carefully examined to search and record any clues. Victim personal, intimate, and professional relationships over a long period are important information. The pre-assault financial and medical condition of the victim can reveal curious individuals and helpful information for the investigation. Criminal and legal history should be obtained from the victim as well as other profile sources available to the investigator. The investigator can establish a very comprehensive picture of the victim before the assault and should then proceed to establish the timeline of the actual attack. The victim should always be asked behavioral questions about the offender. The perpetrator's response to resistance, the manner of approach, and any eccentric utterances may help identify the suspect and are important clues that can establish a case against the offender (Savino and Turvey 2011).

Eyewitnesses and Identification

Eyewitnesses, together with the victim story, are an important part of investigations. Lineups and memory lapses can easily identify the wrong suspect if proper care is not undertaken in examining the eyewitnesses. Similarly, show-ups are even more problematic. If the victim was threatened with a weapon, it is natural for a person to focus more on the weapon than the person pointing the weapon. This may later blur the recognition ability of the victim and eyewitnesses. When the victim and eyewitness accounts support the theory built by the investigator, it is straightforward for the investigator to overlook the reliability and credibility of such statements. They may still not constitute "probable cause" and could weaken the case going forward (Savino and Turvey 2011).

Victim Trauma

The victims of sexual assault often experience trauma. They frequently exhibit symptoms of Rape Trauma Syndrome (RTS) and Post Traumatic Stress Disorder (PTSD). Dworkin et al. (2017) argue that the causal relationship between psychopathology and sexual assault cannot be inferred because sexual assault can lead to psychopathology through various mechanisms. For example, sexual assault can make victims more vulnerable to psychological and mental health problems. The victim can have distorted cognition, a state in which the victim overestimates the danger. History of assault can change the mood by increasing fear and sadness in the victim. Sexual assault can also alter the behavior of a person. The victim may feel more socially isolated or get involved in substance abuse. The authors also found that in cases where a weapon was involved, the trauma level was higher, which demands caution against determining the incident to be a causal relationship. The offender often argues that the trauma experienced by the victim somehow led to a false case, especially when nonconsent is the only major argument dividing the two sides. The investigator should, therefore, reject any defense based on the trauma being caused in a causal relationship that does not exist. This precaution does not suggest that if the victim does not exhibit symptoms of trauma, the psychologist's opinion can easily refute the defense argument.

False Allegations

The false allegation of sexual assault is always a possibility, and many investigators are unaware that false reporting is itself a crime. However, even when an investigator is aware and detects a false report, there are social pressures not to reveal the false report. These pressures come from various social organizations, prosecutor offices, and even colleagues because they believe that pursuing such a case is not worth the time and effort, or that type of inquiry goes against the strict guidelines issued by the department to pursue false reports. The reasons for false reporting range from material profit to simple anger and revenge. Sometimes concealment of illicit relations or illegal activity by a domestic partner is the cause behind falsely reporting a sexual assault when none had occurred or was carried out by the intimate partner, which can be embarrassing. In some cases, the false reporter has actual mental issues that result in falsely reporting an assault (Searles and Berger 2018; Chisum and Turvey 2011).

Reconstruction and Physical Evidence

The investigator needs to examine all the evidence and reconstruct the crime scene so that every part of the puzzle falls in its place. Reconstruction is further strengthened by physical evidence obtained through DNA. Sometimes, sexual assaults are facilitated using drugs. These cases require an additional piece of evidence to complete the investigation.

The main elements of crime scene reconstruction, interviews, and crime scene preservation should be established. A forensic examination of the victim is a functional responsibility. World Health Organization (2003) has issued detailed guidelines and procedures to be followed by forensic nurses. An important point in these guidelines notes:

> The physical examination of sexual assault victims must be thorough; it will inevitably be intrusive and time-consuming. In the interest of avoiding multiple examinations and further distress for the patient, the medical examination and forensic evidence collection should, when possible, coincide. Obtaining informed consent for the examination and the release of information to third parties is a crucial component of the service. All parts of the examination should be explained in advance; during the examination, patients should be informed when and where touching will occur and should be given ample opportunity to ask questions. The patient's wishes must be upheld at all times. (World Health Organization 2003, p. 30)

Forensic nurses should also consider the *differential diagnosis*, a diagnosis in which a set of injuries may have more than one cause. The investigator should even document complainant history and toxicology reports. Elements of physical examination, such as injuries, bruises, and full body examination, should also be carefully recorded (Savino and Turvey 2011).

Drug-facilitated sexual assaults are widespread and pose their challenges for the investigators. Apart from common "date-rape" drugs, such as Rohypnol and GHB, other drugs can also be used. Rohypnol is a depressant of the central nervous system. Within 15–30 min of ingestion, the victim starts showing effects that quickly peak in about 2 h and can easily last as long as eight to 12 h. The victim shows dizziness, visual confusion, decreased blood pressure, and drowsiness. GHB decreases inhibitions, thereby stimulating female victims to behave increasingly flirtatiously. Higher doses can lead to sleep and loss of memory. Drug-related assaults differ from other sexual assaults as the victims are rendered unable to consent due to impairment. The victim participation may seem consensual but is manufactured using drugs. The social context and the motives of offenders are also considerably different from traditional assault motives. The investigator should carefully determine whether the elements of occurrence can be considered a sexual assault or rape under statutory definitions. These include whether the victim was actually under the influence to not have consented legally, whether the participation in a sexual act was voluntary or forced by drugs, and whether the offender had access to the drug in question or not (Sexual Assault Prevention and Awareness Center 2018).

DNA technology has radically changed forensic science. Law enforcement has developed CODIS (Combined DNA Index System), which serves as a data bank for DNA matching. DNA match is great news for the investigator, but due care is needed to expand its use. Suspects who are matched may not be actual offenders, especially when DNA is not recovered from the victim's body. Biological evidence can degrade. Therefore, the body should be transported and preserved in a manner that doesn't render it useless as evidence. Semen, sweat, blood, sperm, trace skin, and bodily excretions are conventional sources of DNA. In some cases, such as acquaintance rape, DNA evidence is of no use to the investigator. DNA evidence should be further supported by the conditions of transfer, and other evidence or reconstruction of the crime scene (Chisum and Turvey 2011; Savino and Turvey 2011).

Offender Psychoanalysis

Sexual assault is not purely a crime with sexual motivations only. Offenders can have different motives and may be serial criminals. The motive is different from intent. A motive of revenge may result in different crimes. For example, people rob, kill, or assault in revenge. The intent is the actual action, which translates to a crime. Someone with a motive for revenge will then intend to commit a crime. The motive helps an investigator to put the sexual assault in perspective and boosts the case against the offender. It also helps look at other evidence which may be ignored if the investigator only focuses on the crime itself.

The offender can be divided into different categories based on motive. An *instrumental* offender is motivated by financial or material ends. These offenders are methodical and plan their crimes. On the other hand, the *expressive* offender is motivated by emotions, jealousy, anger, or purely sexual desire (Chisum and Turvey 2011). *Developmental* issues can turn a person towards committing sexual crimes. Beauregard et al. (2004) argue that there are three types of developmental issues: inappropriate family sexual environment, use of pornography and sexually explicit material during childhood, and resulting deviant childhood fantasies about sex. Many other typologies rely on factors other than sexual, such as power or entitlement (Chisum and Turvey 2011, pp. 387–403). While these typologies are helpful tools in assessing the offender, the investigator can often misdirect the effort by solely classifying an offender under one of these categories. Human behavior may change over time, and there may be many other contributing factors, such as mental illness and sexual gratification.

The investigator should pay close attention to the five steps involved in a sexual assault. The offender first selects the target. Once the victim is identified as a target, the offender tests the victim through some implicit sexual advances (if an acquaintance) or analyzes the victim's routine (if a stranger). The offender then threatens the victim and terminates the assault. These acts may happen very quickly or, in some cases, may

unfold over months, all yielding important information about the offender. Some serial offenders use a particular signature or modus operandi. This can connect many offenses to a single perpetrator or previously committed nonsexual crimes to a sexual assault (Savino and Turvey 2011).

Conclusion

Investigation of sexual assault is different from other criminal investigations in many ways. The investigator should not allow preconceived ideas about sexual assault to guide the investigation. The first response is critical as this enables an investigator to record and preserve important physical evidence. Crime scene and DNA evidence should be carefully documented and thorough enough to allow reconstruction of the crime scene. The handling of victims is challenging because of the emotionally traumatic nature of the sexual crime. The investigator's prime source of information is the victim statement and the evidence obtained from the victim's body. The modus operandi of offenders and serial criminals pose their challenges. Specialized knowledge of conducting sex-related crime investigations can significantly help the investigator to arrive at the truth. It is recommended that the investigator take a step-by-step, detailed approach to analyze every aspect of the crime.

Investigations: Terrorism

James M. Duggan and James J. F. Forest
Center for Terrorism and Security Studies, University of Massachusetts Lowell, Lowell, MA, USA

Keywords

Terrorists · Terrorism · Investigation

Definition

As explained in the ▶ "Criminals: Terrorists" chapter of this volume, terrorists are criminals who commit or directly support acts of violence in order to achieve some type of sociopolitical objectives. An important distinction made in any potential law enforcement investigation is that a "US person" (USPER) is any US citizen or alien granted permanent residency (colloquially known as a "green card").

Introduction

The organizational and operational frameworks within which terrorism investigations are conducted have been significantly enhanced since the attacks of September 11, 2001. Though most will agree that the assorted measures to improve our national security have succeeded in their intent, critics decry the changes as intrusions upon our civil rights and liberties (Chang 2014). Conversely, some may question why the FBI didn't do more in certain instances to protect the USA from harm inflicted by terrorists, just as the FBI bemoans the legal constraints placed upon their tactics and methods to protect the homeland from terrorists. At minimum, the balance between the rights of the individual and the need for a secure homeland was shifted away from civil rights and liberties and toward security in the wake of the attacks of September 11, 2001 (Chang 2014). This chapter will examine some of those changes and leave it to the reader to decide whether the various enhancements went too far, or perhaps not far enough.

Additionally, this chapter will explore the organizational and operational structures that were created or modified since 2001, as well as the legislation and FBI policy and procedures that drive the investigation of terrorists by US law enforcement. Although local and tribal officers are certainly capable and not prohibited from conducting terrorism investigations, only federal agents and duly authorized task force officers (TFOs) may make applications to the Foreign Intelligence Surveillance Court, and the established framework for terrorism investigations suggests that those investigations should be conducted by the FBI's Joint Terrorism Task Forces (JTTFs), in which state, local, and tribal officers participate as TFOs (ODNI fact sheet). This chapter will therefore focus on terrorism investigations conducted within the framework established by the federal government.

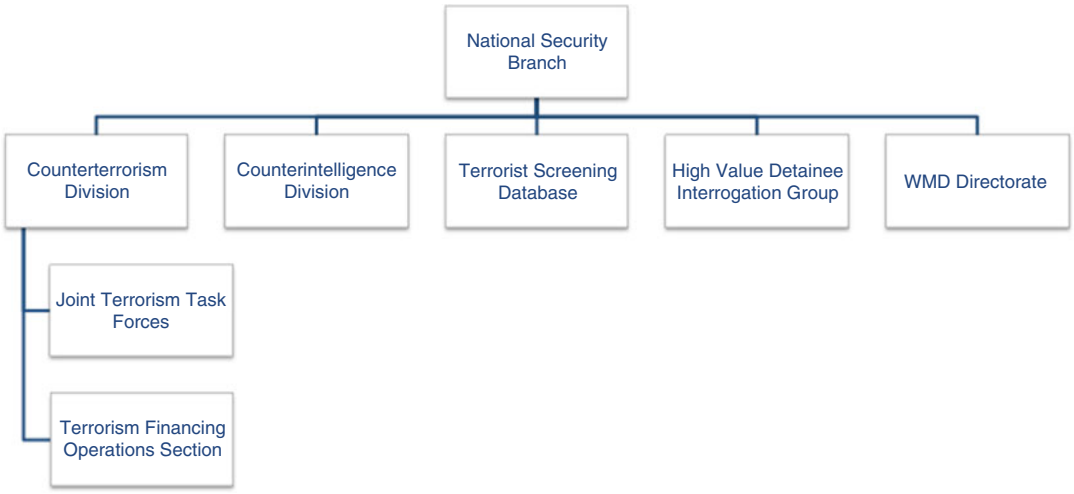
Organizational Structure

The Department of Justice (DOJ) encompasses numerous agencies and divisions that contribute to the US government's efforts to investigate terrorist-related offenses. The DOJ's National Security Division was established in 2006 with the passage of the USA PATRIOT Reauthorization and Improvement Act and tasked with the primary responsibility of combating terrorism (FBI NSD). The National

Security Division coordinates the collective counterterrorism enforcement efforts of their subordinate agencies and others, including the various US Attorneys' Offices, the National Security Branch of the FBI, and the various agencies of the collective US intelligence community (IC), which are discussed in the ▶ "Intelligence" chapter within this volume (FBI NSD). In addition, the National Security Division provides guidance to prosecutors relative to the use of classified information in the criminal prosecution of individuals charged with terrorist offenses and leads DOJ efforts to counter terrorist financing and money laundering (FBI NSD).

The FBI is a vital component of the DOJ and is subordinate to the NSD. The primary responsibility of the FBI is to protect the USA from terrorist threats (USA PATRIOT Act). Per order of a Presidential directive, the FBI established their National Security Branch (NSB) in 2005 to organize the Bureau's national security assets under one umbrella (FBI NSD). The NSB is comprised of five groups and divisions which are disaggregated by area of expertise, allowing the FBI to appropriately assign cases after determining if the subject of investigation is primarily an intelligence or criminal matter (FBI NSD). As discussed in the ▶ "Criminals: Terrorists" chapter within this volume, the lines between terrorists and criminals have become increasingly blurred as terrorist organizations turn to crime to fund their operations and collaborate with criminal groups for incident-specific assistance such as document forgery, smuggling weapons or personnel, and other forms of logistical support (Forest 2013).

The NSB organizational unit (see Fig. 1) most narrowly focused on investigations of terrorism is the Counterterrorism Division (CTD), which oversees the Joint Terrorism Task Forces (JTTFs) and Terrorism Financing Operations Section (TFOS). The FBI's JTTFs are the primary mechanism for investigating terrorist activity within the USA and are comprised of special agents from 55 federal law enforcement agencies as well as state, local, and tribal officers (FBI JTTF). Each JTTF aims to identify and disrupt terrorist threats (FBI JTTF), whether by arrest, administrative actions available to the many agencies involved in the JTTF, or other creative solutions such as the facilitation of mental health treatment. To develop a criminal investigation and collect the requisite evidence while simultaneously managing the threat posed by aspiring terrorists is a daunting task that most often results in a quiet disruption by means other than an arrest. There are currently 104 JTTFs nationwide, 71 of which have been established since the attacks of September 11, 2001 (FBI JTTF). The TFOS



Investigations: Terrorism, Fig. 1 Components of the FBI National Security Division most narrowly focused on terrorism investigations

collaborates with the IC and global partners to identify, investigate, disrupt, and dismantle terrorist financing and money laundering networks throughout the world (FBI NSD).

Other components of the NSB are the Counterintelligence Division (CID), the High-Value Detainee Interrogation Group (HIG), the Terrorist Screening Center, and the Weapons of Mass Destruction (WMD) Directorate. The CID investigates the espionage activities of foreign governments (adversaries as well as allies) and their representatives to identify and disrupt their efforts to steal intellectual property from the US government, businesses, and universities (FBI NSD). Stolen trade secrets and intelligence present opportunities for hostile actors, including terrorists, to develop weapons and technologies that may be used in attacks against Americans in the USA and abroad (FBI NSD). Cyber intrusions have become an especially appealing mechanism to steal intelligence and trade secrets and have therefore become a primary focus of CID (FBI NSD), in collaboration with the National Security Agency (NSA) (Sinai 2014).

The HIG is administered by the FBI and is comprised of special agents, linguists, subject matter experts, and interrogators from various IC agencies that are deployed to conduct effective interviews of high-value detainees in a manner that is consistent with the rule of law (FBI NSD). HIG personnel consistently collaborate with researchers from academia to stay abreast of the latest, most effective interview techniques, as well as to contribute to research on interview techniques (FBI NSD). The HIG deploys Mobile Interrogation Teams to the field during emergent situations and may be used to collect intelligence as well as evidence to be used in a criminal prosecution (FBI NSD).

The Terrorist Screening Center is another multi-agency effort that is administered by the FBI and manages the Terrorist Screening Database, colloquially known as "The Watchlist" (FBI NSD). The Terrorist Screening Database provides an effective early warning detection system at ports of entry and during the processing of visas by the Department of State by compiling and managing a single list of subjects that the government has determined are, or have an association to, known or suspected terrorists at the level of reasonable suspicion (FBI NSD). The Terrorist Screening Database essentially provides a one-stop shopping list of known and suspected terrorists for law enforcement.

The WMD Directorate is the fifth component of the FBI's National Security Branch. The WMD Directorate was established in 2006 and is tasked with proactively preventing chemical, biological, radiological, and nuclear (CBRN) materials and weapons from entering the USA, to identify and disrupt the intended deployment of CBRN materials and weapons, and to respond to incidents involving CBRN materials (FBI NSD). In addition, the WMD Directorate is responsible for establishing and managing "tripwires," which are a staple of our national security and conducted via education and collaboration with private industry, academia, and public health organizations to identify suspicious inquiries or purchases of materials indicative of the collection of materials, knowledge, or expertise necessary to launch an attack (FBI NSD).

Operational Framework

National SAR Initiative

The National Strategy for Information Sharing was enacted by President George W. Bush in 2007 to standardize the collection, handling, and dissemination of suspicious activity reports (SARs) to maximize the utility of the reports and assure that civil rights and rights to privacy are adhered to (ODNI fact sheet). A primary component of the National Strategy for Information Sharing is the National SAR Initiative (NSI). Incidents and behavior reasonably believed to be consistent with international or domestic terrorism justify the documentation of a SAR (ODNI fact sheet). The NSI establishes roles and responsibilities, as well as workflows, for the collection, handling, and dissemination of SARs among the various federal agencies, as well as state, local, and tribal agencies (ODNI fact sheet). Suspicious activity reporting involves one or more of the 79 fusion centers located throughout the USA. These fusion centers are primarily staffed and managed by state police agencies, but many

Incident, Behavior of Concern Reported to Fusion Center
Suspicious Activity Report
Information Sharing Environment
Joint Terrorism Task Force

Investigations: Terrorism, Fig. 2 National SAR Initiative reporting process

also incorporate embedded FBI (FBI JTTF) and Department of Homeland Security intelligence analysts that are provided initial visibility of, and the opportunity to contribute to, the SAR. The standardized procedures require that these fusion centers collect SARs from the public and local law enforcement, as well as private industry partners, most important of which are those responsible for critical infrastructure and key resources (ODNI fact sheet). Law enforcement professionals assigned to the fusion center then examine the reported activity to determine if it meets the SAR standards and if so, document the reported incident or behavior as a SAR (ODNI fact sheet). The completed SAR is then disseminated to the appropriate federal, state, and local agencies (see Fig. 2) via the "Information Sharing Environment" (ISE) that is provided by the FBI's Internet-based eGuardian portal that is available to law enforcement agencies across the country (ODNI fact sheet). The ISE makes the SAR available to other agencies for their situational awareness and reviewed by the FBI's Counterterrorism Division for final determination of whether the reported activity or behavior fits SAR criteria. If deemed a fit with established criteria, the SAR is then assigned via Guardian (classified version of eGuardian) to the appropriate JTTF for investigation. Various laws and policies intended to assure adherence to privacy and constitutional rights throughout the established process are incorporated into the NSI (ODNI fact sheet).

Legislation, Policy, and Procedures

Foreign Intelligence and Surveillance Act (FISA) of 1978

The FISA of 1978 was passed by Congress in response to the revelation that the FBI had been employing wiretap and other electronic surveillance technologies domestically against USPERs for decades (Golden 2014) under the guise of national security. FISA established guidelines and protocols to assure judicial oversight by the Foreign Intelligence and Surveillance Court for the employment of such technologies by federal law enforcement against USPERs (Golden 2014). Among the limits established by FISA were that the target of the surveillance must be either a foreign power or the agent of a foreign power and "that no United States person may be considered a foreign power or an agent of a foreign power solely upon the basis of activities protected by the first amendment to the Constitution of the United States" (FISA 1978, p. 9).

USA PATRIOT Act

The Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism (USA PATRIOT) Act of 2001 (PATRIOT Act) was a direct response to the attacks of September 11, 2001, and shifted the focus away from protecting civil rights, which had been established by FISA, and toward a prioritization of national security (Chang 2014). Proponents of the PATRIOT Act contend that, among other things, the Act makes the country safer by streamlining the legal processes required for judicial approval and allowing for a speedier response by law enforcement to emergent threats while still providing for effective oversight (Hook et al. 2014). Some examples of the changes introduced by the PATRIOT Act (2001) that contribute to law enforcement efforts are roving wiretaps, national wiretap authorization, "sneak-and-peek" search warrants (notice of a search is not provided to the subject), and a change from the requirement that collection of foreign intelligence is "the purpose" of a search or wiretap to the less stringent standard of "a significant purpose" (Chang 2014). Among the arguments offered by opponents

of the PATRIOT Act are that the allowance of sneak-and-peek searches is an intrusion on a tenet of the 4th amendment requiring that law enforcement "knock and announce" their presence prior to entering a place to be searched (Chang 2014).

In the aftermath of the September 11, 2001, attacks, the US government took significant strides to combat terrorist financing and money laundering. Title III of the PATRIOT Act established the International Money Laundering Abatement and Anti-Terrorist Financing Act of 2001 which significantly enhanced the ability of the USA to prevent, detect, and disrupt (by civil forfeiture or criminal prosecution) the flow of illicit funds through US-based institutions (USA PATRIOT Act 2001). Title III prohibits US-based bank accounts from conducting transactions with offshore "shell" banks that did not have a physical address and strengthened the previous Bank Secrecy Act by requiring additional due diligence by banks (USA PATRIOT Act 2001). Due diligence enhancements include confirming the identity of all foreign nationals associated with an account and proactive monitoring of accounts held by foreign nationals or organizations for indications of terrorist financing or money laundering (USA PATRIOT Act 2001).

Policies and Procedures

In addition to legislation regulating the domestic investigative activities of US law enforcement, there are also institutional policies and regulations that must be adhered to. The domestic investigative efforts of the FBI are tightly regulated by the 457-page *Domestic Investigation and Operations Guide* (DIOG), which incorporates guidelines established by the US Attorney General and FBI policies and procedures into a single manual (Federal Bureau of Investigation 2016). The FBI is limited by the DIOG to assure that the least intrusive methods possible are employed at various stages of an investigation, and unless articulable evidence is developed at the earlier stages of a case to justify further investigation with more invasive methods (Federal Bureau of Investigation 2016), the case will be either closed or prosecuted in its current state. Unfortunately, the subjects of closed cases sometimes commit violence, such as Tamerlan Tsarnaev (2013 Boston Marathon bombing) and Omar Mateen (2016 Pulse Nightclub, Orlando attack). As for Mateen, the FBI staunchly defended their prior 10-month investigation of Mateen, insisting they exhausted all legal means of investigation before determining Mateen posed no articulable threat to the public and closing the case (Wilbur 2016).

Though the DIOG may frustrate the good intentions of law enforcement at times, it is necessary for the government to assure that the law and public policy appropriately balance the rights of the individual with the need for national security (USA PATRIOT Act). Closed cases that go awry and result in harm are not necessarily mistakes but may rather be symptomatic of the FBI's adherence to the DIOG, which maintains core values of the USA by favoring the preservation of individual rights over national security. And of course, there is no infallible way to predict what an individual may or may not do in the future.

Characteristics of Terrorism Investigations

The very nature of terrorism necessitates clear distinctions between domestic and international terrorism and the permissible methods to be employed against each (further details of the distinctions between the two can be found in the ▶ "Terrorism: Domestic" and ▶ "Terrorism: International" chapters within this volume). Because terrorism is a form of political violence, domestic issues must be treated carefully to assure that political dissidents are not unfairly targeted (Chang 2014). The *Immigration and Nationality Act* established that the Secretary of State shall compile and maintain the list of designated foreign terrorist organizations (FTOs). To knowingly provide material support to a designated FTO is a criminal offense, but there is no such provision relative to domestic terrorist organizations (USA PATRIOT Act 2001).

For example, in 2006 the FBI indicted 11 members of the Earth Liberation Front (ELF) and the Animal Liberation Front (ALF) that had formed an organization known as "the Family," one of the most prolific domestic terrorist organizations in the history of the USA (Federal Bureau of Investigation, *Eco-terror indictments*). The group conducted a campaign of bombings and arsons that included the Vail Ski Resort, federal land and animal management facilities, private meat-processing plants, and logging operations (Federal Bureau of Investigation, *Eco-terror indictments*). Because the Family was a domestic terrorist organization, they were charged with crimes committed in support of the Family, but there was no specific charge for providing material support to the Family.

As stated previously, many of the cases investigated by the JTTF are predicated upon suspicious activity that was reported to law enforcement. However, although possibly indicative of current or pending terrorist activity, the overwhelming majority of suspicious behaviors and actions that provide the basis for SARs are not illegal (ODNI fact sheet). For instance, it is not illegal to purchase a large amount of fertilizer for no obviously legal purpose. However, such a purchase would likely trigger a "tripwire" established by the FBI's WMD Directorate, generation of a SAR, and assignment to the most appropriate JTTF for investigation at the most appropriate level, most often an assessment (Federal Bureau of Investigation 2016). The inherent difficulty of terrorism investigations is that the JTTF member assigned to investigate the incident does not have the benefit of investigating a past crime, but rather must determine if the suspicious purchase is an indicator of a crime (terrorist attack) to be committed in the future, based largely upon constitutionally protected behaviors and speech.

There have been criticisms of FBI methods and target selection of individuals who have been convicted of terrorism-related offenses. The general basis of the assertion is that defendants who had neither the ability nor means to carry out an attack were "entrapped" by FBI informants and undercover agents who hatched a plot and provided the materials necessary to justify a federal prosecution (Shipler 2012). It is sometimes asserted that the defendant could not have ever collected the requisite weapons or materials without the assistance of the government (Crenshaw and LaFree 2017). However, appeals courts have repeatedly denied these claims of entrapment and violation of due process by defendants, finding that defendants were predisposed to commit the crime and that "…government creation of the opportunity to commit an offense, even to the point of supplying defendants with materials essential to commit crimes, does not exceed due process limits" (United States of America v. Cromitie, p. 57).

Despite the firm legal ground that these counterterrorism investigations may be based upon, judges presiding over trials and appeals have at times expressed concern with the targeting and tactics employed by law enforcement. In sentencing James Cromitie to 25 years in prison for assorted terrorism charges, federal district court judge Colleen McMahon proclaimed that "Only the government could have made a 'terrorist' out of Mr. Cromitie, whose buffoonery is positively Shakespearean in its scope" (Shipler 2012). However, in denying the appeal of Cromitie et al., Circuit Judge Jon O. Newman of the Second Circuit Court of Appeals explained in the majority opinion that once Cromitie had "…expressed a desire to 'do something to America' and had given an ominous meaning to this statement by saying he wanted to die like a martyr, the FBI agents would have been derelict in their duties if they did not test how far Cromitie would go to carry out his desires" (United States of America v. Cromitie, p. 57). Additionally, as noted by Crenshaw and LaFree (2017), many individuals who have carried out successful attacks also seemed to lack the skills and tradecraft necessary to do so, which is especially cogent in an era of attacks with crude weapons such as knives and automobiles driven into crowds of innocent civilians.

Case Studies

Further evidence of the quandary presented by terrorism investigations can be found in case

studies of JTTF investigations. Even as judges periodically express concern with methods employed in some investigations, they also cite the duty of the FBI to investigate those individuals who indicate their desire to cause harm (United States of America v. Cromitie). Most proactive criminal investigations target individuals who are already involved in the prohibited activity, such as drug dealers or arms traffickers, but proactive terrorism investigations require the targeting of individuals and groups who may commit a crime in the future (Shipler 2012). Thankfully, there is a dearth of active terrorist operatives on American streets, leaving investigators to target those who display a risk of attacking in the future (Shipler 2012). The cases targeting James Cromitie and Demetrius Pitts are illustrative of the controversies and difficulties associated with terrorism investigations.

Example 1: USA v. James Cromitie, David Williams, Onta Williams, and Laguerre Payen
The following details of the case of the USA v. James Cromitie, David Williams, Onta Williams, and Laguerre Payen were gleaned from an affidavit submitted by the FBI to the Southern District of New York on May 19, 2009, in support of an application for arrest warrants for Cromitie et al. (Fuller 2009).

In June 2008, James Cromitie, the son of Afghan immigrants, expressed his dismay with US military actions in Afghanistan to a paid FBI informant (CHS – confidential human source) that Cromitie met at a mosque in Newburgh, New York. Cromitie further expressed his desire to do "something to America" and discussed with the CHS how Cromitie would go to paradise if he died a martyr. The two met again on July 3, 2008, and the CHS told Cromitie that the CHS was a member of Jaish-e-Mohammed, a designated FTO based in Pakistan, to which Cromitie responded that he would like to "do jihad" (p. 6). Cromitie recruited three friends (David Williams, Onta Williams, and Laguerre Payen) who began meeting with Cromitie and the CHS at a house in Newburgh that had been outfitted by the FBI with audio and video surveillance equipment. Discussion at the house revolved around Cromitie's desire to attack a synagogue in the Bronx and military aircraft based at the Air National Guard base in Newburgh.

In a recorded conversation on December 5, 2008, Cromitie asked the CHS to get surface-to-air missiles, rockets, or other explosives for Cromitie's future operations and explained to the CHS that they would need to develop code words for future conversations. In April 2009, the CHS, Cromitie, and Williams drove to the Bronx and drove by several synagogues and Jewish community centers, which Cromitie specified would be referred to as "joints" in future discussions. In addition, Cromitie drew attention to a group of people walking outside a Jewish community center and said that if he had a gun, he would shoot each one in the head.

On April 23, 2009, the CHS met with Cromitie and Williams at the Newburgh house where they discussed using surface-to-air missiles to attack aircraft at the Air National Guard base and improvised explosive devices (IEDs) to attack a synagogue. They further discussed code words, as well as the need for cell phones and handguns, which Williams arranged the purchase of with a female gun supplier in the Newburgh area. The CHS coordinated with individuals (believed by Cromitie and the others to be members of Jaish-e-Mohammed) to supply one Stinger missile and three IEDs constructed with c4 explosives and advised Cromitie and the others of the arrangement.

After conducting surveillance of the Air National Guard base and determining the location from which to fire the missiles, Cromitie and Williams engaged in a telephone conversation that was intercepted (the inference is via a court-authorized wiretap of at least one of the devices used for the conversation) in which Williams advised Cromitie that Williams had procured the handguns. However, when the group drove to retrieve the guns, the supplier said she had sold them to someone else. The group then picked up Onta Williams (whom David Williams had recruited to assist with the attacks), bought cell phones for the operation, and after numerous phone calls was able to arrange for the purchase of a handgun.

On April 28, 2009, the group was joined by Laguerre Payen in the Newburgh house and engaged in recorded conversation, in which all declared their willingness to engage in the planned attacks in support of Jaish-e-Mohammed. Onta Williams stated that "they [the United States military] are killing Muslim brothers and sisters in Muslim countries so, if we kill them here [in the United States] with IEDs and Stingers, it is equal" (pp. 10–11). The group then drove toward a storage facility in Connecticut to retrieve the Stinger missile and three IEDs, but Onta Williams thought he detected law enforcement surveilling the group so they returned to Newburgh. Onta Williams was dropped off in Newburgh, and after driving and determining that law enforcement was no longer following them, they drove to Connecticut and retrieved the missile and explosives before returning to Newburgh, where the payload was stowed in a storage facility. All of the defendants inspected the missile and explosives, before practicing with the remote detonator for the IEDs and exclaiming "Allahu Akbar" (praise be to God) as they locked the door to the storage unit. On May 19, 2009, the FBI applied for and was granted arrest warrants from a US Magistrate Judge in the Southern District of New York charging all four co-conspirators with conspiracy to use weapons of mass destruction within the USA, conspiracy to acquire and use antiaircraft missiles, and conspiracy to kill officers and employees of the USA.

All four were convicted and sentenced to 25 years in prison. The case was appealed to the US Court of Appeals for the Second Circuit in 2012 and denied, with one justice concurring with Cromitie's claim of entrapment (United States of America v. Cromitie). However, the two other justices denied all claims made by the defendants, and the sentences of all four were therefore upheld. In their majority opinion, the justices stated, "the principal defendant expressed early on an inclination to commit acts of terrorism and his co-defendants promptly and enthusiastically joined the plot with full awareness that it included launching anti-aircraft missiles. The Government did nothing improper by testing to see just how far these defendants would go in committing acts of terrorism" (United States of America v. Cromitie, p. 77).

Example 2: USA v. Demetrius Pitts

The facts of the FBI's case against Demetrius Pitts were culled from an FBI affidavit filed in support of a criminal complaint charging Pitts with one count of material support to a FTO (Wilson, A.J., United States of America v. Demetrius Pitts). Unlike the previous case, Pitts has not been convicted, but stands accused of the crime with which he is charged, and remains innocent until proven guilty. The Pitts case is illustrative of a typical JTTF investigation predicated upon a SAR.

On July 1, 2018, Demetrius Pitts of Maple Heights, Ohio, was arrested and charged with attempting to provide material support or resources to a foreign terrorist organization in violation of Title 18, United States Code, Section 2339B. Pitts originally came to the attention of the FBI in December 31, 2015, when he sent a private Facebook message to a political television show expressing his contempt for the USA in general as well as the US military, more specifically, and further stated that the USA would be destroyed. The incident was reported by representatives of the television show, which generated a SAR to be investigated (the inference is as an assessment). Legal process served upon Facebook by the US Attorney's Office for the account revealed that Pitts was the user of the account and utilized a pseudonym for the Facebook account.

Pitts did not come to the attention of the FBI again until January 2017, and it is unclear what investigative activities were undertaken in the interim, if any. On January 25, 2017, Pitts commented on images of activities in an al-Qaeda training camp via Facebook, opining that Muslims should be learning how to shoot guns and training every day. Pitts posted, "If you fear death. Then you don't love Islam. . .we should always be prepared to fight in the name of Allah Akbar" (p. 3). Between January 25, 2017 and June 2018, Pitts continued with violent rhetoric via Facebook, which evolved into Pitts expressing his desire to travel overseas to receive training

for an attack to be launched in the USA. In addition, Pitts expressed his aspiration for recruiting others to join him in future attacks within the USA. When Pitts disclosed his desire to meet a "brother" from al-Qaeda, the FBI obliged by assigning an undercover special agent (UCE – undercover employee) to make contact with Pitts and present themselves as an al-Qaeda operative.

On June 15, 2018, Pitts met with the UCE, who conducted a "consensual recording" of the meeting. It is worth noting that Pitts obviously did not consent to the recording, but federal law permits one-party consent, meaning only one individual involved in the recording must consent to that recording. Just as a co-conspirator working on behalf of the government may consent to recording a conversation with the subject of an investigation, the UCE provides the consent in an undercover operation.

In recorded conversation with the UCE, Pitts explained that he wanted to target members of the military, cut off their head and hands, and anonymously mail them to government officials to "make a statement." When the UCE inquired about targeting sporting events and stadiums, Pitts explained that it would be best to target military members who had engaged in combat with Muslims rather than innocent civilians, stating that "These people ain't got nothing to do with it" (p. 5). Pitts acknowledged to the UCE that the brothers may want Pitts to prove himself before they agree to collaborate with him and was clear that he was willing to kill a military member, stating "That's what they signed up for. Look at they signed up for war. Guess what? They want war, we can bring war to them" (p. 8).

One week later, on June 22, 2018, the two met and engaged in another recorded conversation in which Pitts conveyed his interest in launching an attack on the 4th of July. Pitts considered attacking an event in Washington DC but quickly decided there would be too much security and then discussed attacking a parade and fireworks display in downtown Cleveland, Ohio. Pitts suggested they could employ small remote-controlled cars outfitted with bombs to attack the parade. Pitts requested that the UCE get money from the brothers to fund his trip from the Cleveland suburbs to the downtown area so that he may conduct reconnaissance and take photographs and video for the brothers.

On June 25, Pitts met with a CHS posing as an al-Qaeda member who provided Pitts with a bus ticket and a phone to be utilized in his reconnaissance efforts. On June 26, members of the FBI Cleveland JTTF conducted physical surveillance of Pitts as he toured downtown Cleveland, taking photographs and video of potential targets. Pitts contacted the UCE via text message with an update of his activities and began discussing an attack in Philadelphia, telling the UCE that the brother who was making the bombs for Cleveland should continue but they would need more for Philadelphia. Pitts explained to the UCE that he would identify the targets but other brothers would have to conduct the attacks and gave the phone used for the pre-operational surveillance of Cleveland to the UCE, with Pitts' password of "0704."

Later in the day on June 27, Pitts met with the UCE and disclosed that he thought a van loaded with explosives would be the best opportunity for success to target US Marines marching in the 4th of July parade. Pitts reiterated that he would conduct the pre-operational surveillance and the brothers must handle the explosives, but Pitts didn't want to meet the brothers to be involved in the attack for operational security reasons. Pitts provided the UCE with his personal phone that he had also used for pre-operational surveillance and advised the UCE that he would like to be called "Salah ad-Deen," which is Arabic for "the planner." Search warrants executed on the phones revealed two videos of Pitts pledging allegiance or "bayah" to al-Qaeda, as well as photographs and video taken by Pitts. While driving together the UCE and Pitts passed the US Coast Guard base in Cleveland, and Pitts decided the explosives-laden van should be parked immediately adjacent to the Coast Guard building and detonated as US Marines marched past.

The investigation culminated in a July 1, 2018, meeting between Pitts and the UCE in which Pitts pitched his plan for a future attack against the Federal Building in Philadelphia that Pitts felt would "hit 'em in the gut" (p. 29). When the UCE commented that there would be "human carnage"

and "that body parts would be flying around," Pitts explained that he wouldn't have any remorse and wouldn't lose any sleep over the incident. When the UCE showed Pitts a c4-laden remote-controlled car that the purported al-Qaeda bombmaker made for their operation, Pitts suggested they replace the BBs packed with the explosives with cut-up pieces of metal because it is possible to survive the BBs but that shrapnel would "tear you up" (p. 29).

Pitts further suggested that they give the cars to the children of military members as gifts, in the hopes that they would detonate the cars at home. Pitts was then arrested pursuant to a criminal complaint issued by US Magistrate Judge David Ruiz and charged with attempting to provide material support or resources to an FTO. On July 25, 2018, Pitts' public defender advised the court that Pitts has a long history of mental illness and requested a mental health evaluation, a move which was not objected to by federal prosecutors. Magistrate Judge David Ruiz ordered the evaluation (results of which are pending) and explained that the next hearing would be subsequent to the release of the mental health evaluation (Heisig 2018).

Conclusion

Identifying the appropriate balance between civil liberties and national security is a delicate subject that evokes passion on both sides of the argument, and appropriately so, as this strikes at the most fundamental tenets of our democracy. The enhanced tools for law enforcement that were provided through legislation passed since 2001(especially the PATRIOT Act) are alleged by some to have strengthened national security at the expense of liberty (Chang 2014). Conversely, law enforcement is often frustrated by restrictions of allowable methods placed upon them by the DIOG (Wilbur 2016), which is exacerbated by the public's unrealistic expectation of complete immunity from terrorist attack. The fulcrum has shifted throughout time and will continue to do so, as the context of the time and public pressure of the electorate influences political decision-making.

The investigations of Cromitie and Pitts illustrate many of the issues inherent in terrorism investigations. Were Cromitie and Pitts "buffoons" or future terrorists that were appropriately identified and investigated with great diligence by the JTTF before having their plots disrupted by arrest before they could cause harm? Investigation of terrorists requires great skill and judgment, as law enforcement must navigate the laws and policies intended to protect us from unwanted law enforcement intrusions into our daily lives as they tirelessly pursue those who intend to do us harm.

Definition

Fingerprint evidence comprises of the study and comparison of the friction ridge detail that is present on one's fingers, as well as the palms of their hands, soles of their feet, and toes. During daily activity, we leave behind impressions of these friction ridges either through sweat and other material on our hands or contact with a foreign substance such as blood or grease and then touching a clean surface leaving a tracing of friction ridges. These can be collected by crime scene personnel and compared to the friction ridges of known persons or prints collected at other crime scenes in an attempt to determine who contributed these prints. This then confirms to the investigator that this person had to have been present and/or touched this object. In this practice, genetic material is used to answer questions pertaining to the investigation. Often during the course of our daily activity, we leave behind genetic material. This is as simple as remnants of saliva on coffee cups and water bottles, to skin cells on the clothing we wear and items we hold. There are specific types of activity, of which the criminality may be in

question that are more likely to produce and dispose of genetic material. This is most common with sex-related activity and death investigations. These can be collected by crime scene personnel and compared to the friction ridges of known persons or prints collected at other crime scenes in an attempt to determine who contributed these prints. This then confirms to the investigator that this person had to have been present as well as generally how they interacted at the scene. Saliva on a cup would indicate that the person drank from that cup, while semen in a sex assault victim's vagina indicates sexual activity.

Introduction

Fingerprint evidence is one of the best and most probative of all types of physical evidence. It can be used to identify people as well as associate them with locations or objects. It should be sought at crime scenes, especially scenes with unknown perpetrators (James et al. 2014). The forensic science discipline which had made the most strides and gained the most attention in the recent past is that of forensic biology, which is comprised of the disciplines of body fluid identification/serology and DNA analysis. This area can be of great value to investigators and provide information that is both relative and substantial in its investigative and evidentiary value.

Fingerprint

Fingerprint evidence is one of the best and most probative of all types of physical evidence. It can be used to identify people as well as associate them with locations or objects. It should be sought at crime scenes, especially scenes with unknown perpetrators (James et al. 2014).

While still in the womb, the friction ridges are formed and the arrangement of the ridges does not change through one's lifetime. Friction ridge skin is composed of two layers of skin. The outermost layer is known as the epidermis and the innermost layer is known as the dermis. The "blueprint" for an individual's friction ridge skin is rooted in the bottom layer of the epidermis, called the basal layer. As long there is no trauma to the basal layer, an individual's friction ridge skin arrangement will not change. In fact, even if one burns off the top layers of the epidermis with an acid, they will grow back in exactly the same fashion. The only way a fingerprint can be changed is through a traumatic event of the basal layer. Trauma to the basal layer will result in a permanent scar. However, the ridges around the area of trauma will remain the same.

Fingerprint evidence comprises of the study and comparison of the friction ridge detail that is present on one's fingers, as well as the palms of their hands, soles of their feet, and toes. As the name of the discipline implies, the vast majority of this work focuses on the friction ridges on the end of one's fingers. This is the volar skin, and it has a special texturized surface with narrow corrugated ridges, known as friction ridges. They are meant to increase our ability to grip other surfaces with which they come into contact. "Smooth skin contains hair, sebaceous glands and sweat glands while volar skin contains only sweat glands" (Ashbaugh 1999). Latent prints are made when sweat from the volar skin as well as the oils from the subject's face, hair, or other parts of the body are deposited on the hands. The hands then come into contact with another object or surface through touching. Through this contact, the subject may leave their fingerprints behind. Fingerprints, as a medium for identification, date back to pottery in the middle ages as well as to finger and hand seals dating back to BC era.

Despite the advancement of other forensic disciplines, such as DNA, fingerprint evidence remains the workhorse of crime scene and criminalistics. Our fingers come into contact with the outside world more than any other area of our body. Whatever task we set out to employ, it invariably involves touching, grabbing, and moving objects. Thus, latent print work is very effective in crime scene investigation. Whatever the crime, the perpetrator likely touched, held, or moved an object or objects in the perpetration of their acts. This can include things like a knife or gun in a violent crime to a door, window, or safe in a burglary/theft. Even

a paper on which a note was written or a countertop in a bank or convenience store robbery. All of these areas are potential locations of fingerprint evidence.

Fingerprints found at crime scenes are generally separated into three categories. These are plastic, patent, and latent. Plastic prints are three dimensional and exist in pliable surfaces like wax, clay, or putty. These types of impressions are rare as the surface conditions need to be perfect for the formation of a plastic print. Patent prints are areas of friction ridge detail that are visible to the naked eye without any enhancement. These are created when the hand is soiled in a substance with a staining quality and then comes into contact with another surface. This includes situations like prints located in ink, blood, and grease. The last type prints are latent prints. Latent prints are defined as areas of friction ridge detail that are invisible to the naked eye and are only visible after some sort of processing is done to make the fingerprints visible. These are the most common in the field of forensic science to the extent that most crime labs' sections dealing with fingerprints are formally named the Latent Print Unit or Section.

Fingerprint Powders and Processing Variations

The most common way that latent prints are made visible is with the application of fingerprint powder. Fingerprint powder comes in innumerable forms and colors. For our purposes, we will concentrate on those with widespread use and acceptance. The most common colors are black, white, and silver/gray. Fingerprint powder originally only came in black as well as gray and was made with volcanic ash. Volcanic ash was of such a fine consistency that it worked well for latent print use and is still in use to this day in many labs and field units. Regular powder works best on smooth and nonporous surfaces. It is most often applied with fiberglass brushes. Although it should be noted that there is variation here based on the specific powder being used and individual's preferences and habits. The color of the fingerprint powder is chosen simply to create the greatest color contrast with the item being processed. So, if one was processing a dark colored surface, they would use a silver/gray powder. If one was processing a light-colored surface, they would use black powder. Providing the greatest contrast to the background makes it easier for the examiner to see the print and thereby increases the chances of the print being of value.

Another common type of powder is also available in magnetic form. The powder is made with a metallic quality that is attracted to a magnetic applicator. The brush is more of a magnetic wand used to hold and dispense the product. Experienced individuals processing areas for latent prints quickly find the specific uses and benefits of magnetic powder, which came about in the early 1960s. "Textured surfaces such as vinyl imitation-leather or lightly textured automobile dashboards or door panels often respond well to magnetic powder, where regular powder would pack into the low places in the texturing and make development of a good latent impossible" (Minutiae, the Lightning Powder Co 1997). Another distinct advantage of magnetic powder is that it is safer to use since "there is no brush with fibers to touch and possibly damage the print. The powder … is attracted by a magnet and carried as whiskers by a magnetic wand. Nothing but the powder itself touches the print" (Minutiae, the Lightning Powder Co 1997). Like traditional powder, magnetic powder comes in many varieties and colors.

The last category of fingerprint powder is fluorescent. This type of powder is available in both the traditional and magnetic forms. The difference with fluorescent powder is that it fluoresces under the correct wavelength of light. Fluorescent powder is highly beneficial when you are looking for prints on an item with a colorful or distracting background. As was stated earlier, they key is to provide a contrast for the examiner. If the background is simply too colorful or patterned to have a contrast, then fluorescent powder can be used. The drawback here is that an Alternate Light Source is needed to cause and view the fluorescence of the powder. This is similar to an ultraviolent (blacklight) light used to locate items that fluoresce.

Cyanoacrylate fuming is another important step in fingerprint processing methodology. Cyanoacrylate fuming is also commonly referred to as super glue fuming because cyanoacrylate is the main ingredient in superglue. This is most common with smaller moveable items that can be transported back to a crime laboratory for fuming in a designated fuming chamber. Items are placed in the chamber and then cyanoacrylate vapors are introduced to the chamber. These vapors are attracted to the amino acids that make up the friction ridge impression. The vapors adhere to these areas and polymerize. This makes the prints much more durable and less susceptible to accidental destruction. The greater stability also allows a criminalist to employ other processing techniques that would otherwise destroy a latent print, such as dye staining. Dye staining is another technique to visualize latent prints with the use of an alternate light source tuned to a specific wavelength.

There are other processes that will develop prints on a variety of surfaces. Chemicals like ninhydrin and iodine can be used on paper and porous surfaces like raw wood or cardboard. Cloth, fabric, and other flexible and overly porous items are generally not-conducive to latent print development. If areas of friction ridge detail are located on these surfaces, it is most commonly a patent print.

Areas of friction ridge detail can be collected and preserved through a variety of techniques. Prints in powder can simply be lifted with fingerprint tape or hinged lifters. This is not unlike thick packing tape where the adhesive side is placed over the developed print. The tape is then removed and the powdered print is then adhered to a background that contrasts in color to the powder used. There are also lifting techniques that work better for curved or textured surfaces such as lifters with a gelatin quality and silicone casting materials such as Mikrosil. One of the best and increasingly prevalent ways of collecting a latent print is through photography. This requires a trained Forensic Photographer as there are a number of photographic as well as legal considerations. However, this method is preferred as it captures the truest form of the friction ridge detail. Destruction of the print through a mishap or mistake in the lifting process is not a concern, and it is able to be digitally enhanced without a need to scan in the image. With nearly all plastic prints and some patent prints, photography is the only means to preserve the area. This is especially true if the print is on a large item that cannot simply be removed and brought to the lab, like a wall in a house. Prints that that require a specific light source, such as those developed with fluorescent powder or dye stain, can be photographed in their state of fluorescence, thereby eliminating the need for an examiner to fluoresce the print in order to view it.

Latent Print Examiners and Examinations

Once an area of friction ridge detail is located and collected, it is provided to a latent print examiner. This person will conduct a qualitative and quantitative analysis of the area of friction ridge detail. This is completed to determine if the print has enough detail and is of sufficient quality to conduct an examination. If the print is sufficient, it can be compared to other areas of ridge detail. It is standard practice to submit known print exemplars of victims and/or other individuals who may have left the print unrelated to the crime. This way, an examiner can determine if the print is that of a possible perpetrator or not. For example, in a burglary, if a crime scene team locates fingerprints on a safe where money was taken, they do not know if they recovered the prints of the perpetrator, or simply prints left by the homeowner/victim from the accessing the safe in their normal course of business. The latent print examiner needs the prints from all the people who had lawful access to the item to make sure it was not one of their prints that happened to be located and collected. By eliminating these individuals as the source of a fingerprint, it may be reliably presumed that the fingerprint was likely left by the person who perpetrated the crime, although that cannot be completely assumed and will need verified by the investigators.

Once this is completed the examiner can look at the prints and compare them to possible perpetrators of the crime in question. This can come in a variety of ways. Investigators may submit prints of possible suspects that were acquired in the course of their

investigation. Note that this would require suspects to willingly provide exemplars of their fingerprints, or a search warrant to have been granted that would allow the police to recover the known exemplars. Many state agencies have databases of known fingerprints and palm prints generally known as Automated Fingerprint Identification Systems or AFIS. In the United States of America, the FBI maintains a database of fingerprints and palm prints known as the Next Generation Identification System (NGI). This database includes submissions from all states and the municipalities located within them. A section of this database is the recorded fingerprints and palm prints taken when one is arrested and goes through the booking phase to verify and ensure that the identity is correct. As such, an investigator may ask an examiner to compare the fingerprints recovered from the scene to a suspect's fingerprints that are on file in an AFIS or NGI database from a previous arrest. If there are no suspects, then an investigator can request that the fingerprints are searched in AFIS or NGI against the entire database. Here the computer-assisted search can provide the examiner with a list of possible people who have similar prints. It does require an examiner to then evaluate the list of candidates provided by the computer and determine if there is in fact an identification. This is a common misconception by the public, who assumes from television and movies that the computer itself makes identifications. The computer only provides a list of potential matches and cannot make any final determinations.

When comparing a latent print to a known print, the examiner does a qualitative and quantitative analysis of the friction ridge impressions. Here an opinion is formed as to if there is sufficient uniqueness to eliminate all possible donors except this one. (Smooth skin contains hair, sebaceous glands and sweat glands while volar skin contains only sweat galnds.) Their opinion of identification is a subjective conclusion and may be expressed in different terms depending on their training, skill, agency procedures, and experience.

It should further be noted that the common practice in fingerprint laboratories, and a requirement in accredited labs, is that another examiner verifies the findings of the initial examiner. The practice most commonly followed is referred to as ACE-V. This stands for analysis, comparison, evaluation, and finally verification (Ashbaugh 1999).

The ACE-V process begins with simply the ACE portions which can contain multiple sessions of all three portions: analysis, comparison, and evaluation. Initially, the first print (the unknown or latent print) is analyzed. Next, the second print is analyzed, as needed. These are then compared to each other. "Eventually, the final analysis and comparison lead to the final evaluation. Many influences can affect the current ACE examination" (Vanderkolk 2011). This includes "knowledge and beliefs of uniqueness, persistency, and impression evidence in other types of forensic comparative sciences can influence the examination. Biases, pressures, or expectations can influence the examination. The examiner needs to be aware of other influences and conduct the examination so that these influences do not negatively affect the examination" (Vanderkolk 2011).

The verification is a form of peer review to verify the process and the objectivity (Ashbaugh 1999). This is a checkpoint necessary with the subjective nature of fingerprint comparisons. This can be done multiple ways and blind verifications where the initial examiner's findings are not revealed to the verifying person has become the method most recommended. This eliminates the chance of bias. It should be noted that these processes are very case specific, and it can be a fluid practice.

Forensic Biology/DNA

The forensic science discipline, which had made the most strides and gained the most attention in the recent past, is that of Forensic Biology, which is comprised of the disciplines of body fluid identification/serology and DNA analysis. This area can be of great value to investigators and provide information that is both relative and substantial in its investigative and evidentiary value. In this practice genetic material is used to answer questions pertaining to the investigation. Often during the course of our daily activity, we leave behind genetic material. This is as simple as remnants of saliva on coffee cups and water bottles, to

skin cells on the clothing we wear and items we hold. There are specific types of activity, of which the criminality may be in question that are more likely to produce and dispose of genetic material. This is most common with sex-related activity and death investigations.

Forensic Biology starts with and was preceded with a forensic discipline called Serology. This is the process of examination and analysis of different bodily fluids, blood included (James et al. 2014). Serologists verify that material collected at a crime scene is actually a body fluid such as saliva, semen, urine, or blood. In the case of blood, they may confirm that it is human, or some other species. It should be noted that often these are stains and can be degraded or deteriorated, making these process more difficult and separating serologists in forensics with the comparable practice in the medical field (James et al. 2014). Traditionally, this process was necessary before the material could be submitted to a DNA lab. In current day, some labs have a straight to DNA approach with items that do not need verification or clarification as to the substance submitted.

DNA broke into the world of forensic sciences in the 1980s and prior to this blood was only used to determine blood type (ABO) and thereby could eliminate or include individuals to the suspect pool. DNA is a long molecule in the cell in the form of a twisted ladder that is called a double helix. For the purposes of forensic identification, they focus on Short Tandem Repeats (STR). It should be noted that in the past this was done through RFLPs (Restriction Fragment Length Polymorphism), which an investigator may find in lab reports or evidence from older cases. The invention of Polymerase Chain Reaction (PCR) allows a scientist to amplify DNA. PCR is a technology that copies short segments of DNA millions of times in a process that resembles the way DNA is duplicated in the body (Fisher 2004). This is what has permitted scientists to have success with very small samples of bodily fluids recovered at a crime scene.

In a sexual encounter, there is likely to be a swapping and disbursement of body fluids. This includes saliva from kissing, licking, or holding items in one's mouth. In an investigation, this fluid can be recovered directly from the item kissed, licked, or held in the mouth as well as from surfaces that quickly thereafter came into contact with said item. For example, in a sexual assault, a woman is forcibly pulled into an alley. Then male perpetrator pulls down her shirt and bra and licks her bare breasts. He then exposes his penis from his pants and underwear and has her perform oral sex on him against her will. They are interrupted. He returns his penis to his pants and underwear and flees the area. She covers her breasts back up with her bra and shirt then seeks help. In investigating this crime, the perpetrator's DNA may be able to be recovered from the saliva he deposited onto the victim's bare breasts as well as the inside of her bra from when she returned her breasts to her bra – postassault. This can be especially beneficial of she bathes or otherwise cleans herself prior to a forensic examination. If the suspect is apprehended, the victim's saliva could possibly be recovered from his penis. Similarly, if this is not possible or able, there is a likelihood that some of her saliva may have been deposited on the inside of his underwear when he returned his penis to his underwear – postassault. Had they not been interrupted, and the suspect had ejaculated then there would also be the ability to collect his DNA from the cells in the ejaculate. If this is recovered at the scene, then it ties the suspect to the scene where it occurred. If it is on the victim's clothing or body, it helps to tie him to the victim due to the location of its recovery. It is extremely important for investigators to note from where samples were located and recovered. Had this hypothetical assault included any activity with the victim's vagina then the presence of vaginal fluid could also be possible. If the suspect would have penetrated her vagina with his fingers, or an object then it becomes possible to potentially locate traces of her vaginal fluid. This could be on the suspect's fingers or penis, or an object that may have been used to penetrate her vagina. If it is on the suspect's body and he has time to clean himself or there is a delay in time between the assault and his capture, it becomes increasingly likely that the fluids will have been washed off. However, with an object it may remain and that could help to tie him and the object to the assault.

Seminal and vaginal fluids are particularly probative to an investigation of a sexual nature because these fluids are only present due to sexual activity. Blood, saliva, and skin cells can be left behind through completely innocuous activity. This is not the case with seminal and vaginal fluid. There is a challenge for the investigator in that the presence of this fluid can confirm the activity occurred. If seminal fluid or spermatozoa are located on the orifice swabs collected in a sexual assault collection kit, then we know that penetration occurred (Fisher 2004). It does not prove that there was or was not consent, or specific motives and intent in behavior that may be criminal. Urine is also a substance from which genetic material can be processed evidentiarily, but with some difficulty.

While forensic biology plays a crucial role in crimes like sexual assaults, it is not limited to those types of crimes or investigations. Genetic material can be recovered from a number of situations. If someone is receiving threatening letters, they can be examined for saliva from licking the envelope. Burglary often requires force to enter the home or business. During this force, it is not uncommon for a perpetrator to injure themselves. This can be from shards of glass in a broken window to an injury sustained prying a lock open. This creates a situation where blood can be recovered from the scene. Moreover, this blood can tie them to the specific activity related to gaining entry if it is located there. If blood is found on the edge of broken glass, then in can be inferred that the suspect cut themselves on the broken glass as it could not have been deposited there prior to the glass being broken. The same holds true for any point of forced entry where damage occurs that did not previously exist.

Touch DNA has become a common topic in the evolution and advancement of DNA technologies. DNA testing originally required a larger sample that it currently does. The development of touch DNA has dramatically increased the number of items of evidence that can be used. In the 1980s, in order to perform DNA analysis forensic investigators needed a blood or semen stain about the size of a quarter (Houck and Houck 2008). With the advancement in the ability to amplify collected samples, labs have been able to process much smaller samples. This has allowed the testing on a small number of epithelial cells shed from the handler's skin. We are constantly shedding skin cells throughout our life and in our activities. Some of these activities allow for a more concentrated deposit, which can open the door for DNA testing. The best example of this is the clothing we wear. A shirt collar has constant and prolonged contact with your body. As such, it is an excellent potential source of touch DNA. The same principle applies to other clothing which has prolonged contact with your skin, to include hats and gloves. Hats and gloves are more commonly discarded and left behind, therefore becoming frequent objects collected during investigations. Items which are held for significant periods of time are likewise candidates for Touch DNA processing. For these though it is important that the item has a textured surface that is able to hold the skin cells and also that the person in question held it for a significant period of time or utilized it with a significant amount of force. A smooth item like a doorknob or a piece of silverware is unlikely to have an area capable of holding skin cells. Contrastingly, items like the checkered handle of a firearm or a rubber texturized grip of an aluminum baseball bat have a better chance of retaining shed skin cells. Even if the item has this textured surface, it is crucial that the person in question hold the item for a significant period of time. If one merely handles an item or only has it for a few minutes, it is unlikely that they would shed enough cells in that period of time to leave behind enough of a sample to yield any results. Other names for Touch DNA that can be more accurate are "Wearer DNA" or "Prolonged Contact DNA."

Once an item has been collected for potential DNA or a swab of a substance believed to be genetic material is submitted to a crime lab the first place it is analyzed is the Serology Section. That is unless, the lab's practices follow the direct to DNA approach mentioned above. Scientists in this section will screen the items or samples for the presence of biological materials. This is most commonly done visually, chemically, immunochemically, and microscopically. Alternate

Light Sources, which utilize specific wavelengths of visible light as discussed earlier in Latent Prints, are used here too, as many biological fluids fluoresce. Confirmatory tests can verify that the item is what it is presumed to be, such as blood, semen, and saliva. Urine can be screened for substances commonly found in urine. Some body fluids can also be verified as human and not from another species.

The most common form of DNA in forensics is nuclear DNA. These samples go through a four-step process of extraction, quantitation, amplification, and detection. The lab targets regions along the chromosome known as short tandem repeats (STR). This STR genetic profile can then be compared to other known genetic profiles. This can include profiles of the victim, suspect, or other involved parties. Through this comparison, a scientist can include or exclude individuals as contributors. If there are no known persons or samples with which it is to be compared, there is a database maintained by the government against which it can be searched, if the sample meets the criteria established by the FBI. This is known as CODIS, which is the Combined DNA Indexing System. Profiles can be uploaded to CODIS which will search the unknown profile against convicted offender and arrestee profiles, as well as unknown profiles from other open cases. If a hit occurs, then the laboratory will be able to provide either the name of an arrestee or convicted offender, or case information from a related case, as an investigative lead. So, if investigating a serial rapist, the investigators can determine other crimes that this person has likely perpetrated, or even other agencies that may be investigating the same unknown individual for like or other crimes.

Mitochondrial DNA is most commonly used where the DNA samples lack the quality or quantity for Nuclear DNA testing. mtDNA can come from items such as bone, hair, or environmentally damaged samples. mtDNA only follows the maternal lineage. mtDNA can be used in missing persons cases or with samples that are old and degraded where nuclear DNA in not present (Fisher 2004).

DNA processing can generally do several things to aid an investigation. It can link suspects and victims not only to each other, but also to the scene themselves of objects used in the commission of the act in contention. They can include or exclude individuals as suspects or victims. DNA processing can also help to establish the crime scene or where an act occurred as well as corroborate circumstances relevant to the case.

Conclusion

Despite the advancement of other disciplines in the forensic science arena, fingerprints continue to be the workhorse as the most used and widespread applicability through various criminal activities. While fingerprints is the most common forensic practice, DNA is the quickest advancing discipline and the one with the greatest future potential in scientific advances. There are already scientists getting more detailed results from samples and working on new techniques to gain useful information from smaller or degraded samples. The realm of DNA evidence is expected to continue to grow in its usefulness in criminal investigations.

Definition

Administrative law is the branch of law governing the creation and operation of administrative agencies. It is also a body of rules, procedures, and principles created by government agencies and departments in order to carry out laws created by courts (*case law*) and legislatures (*statutes*).

Introduction

This entry summarizes federal and state/territorial administrative law as it affects security management and emergency management (McKinney 2018). Federal administrative law primarily concerns the powers and procedures of federal administering agencies in relation to the public (but usually not in criminal matters). It is the Congress that grants general and specific powers to various federal agencies through enabling legislation as well as the general laws for their fair and orderly administration. These executive powers are often quasi-legislative in nature (via rules and regulations applicable to a class of persons or organizations) or quasi-judicial in nature (via orders, adjudications, and decisions involving particular persons or organizations). The given powers are also subject to judicial review and interpretation. As industry and technology grew over the past 125 years, the Congress deemed it appropriate to delegate the details of administering laws to protect the public or enhance fairness to executive departments or independent regulatory agencies. Unlike the heads of executive departments and agencies, the heads of independent regulatory agencies generally do not serve at the pleasure of the president or have their rules and legislative recommendations reviewed first by OMB [Office of Management and Budget]. The first independent regulatory agency was the Interstate Commerce Commission established in 1887 (McKinney 2018).

Powers of Enabling Statute

An *enabling statute* may create an agency, authorize rulemaking, and empower agency rule enforcement. At the same time, other laws in the agency's expertise area may be enforced by the agency and then become agency standards and rules. Procedural rules are laws of agency methods and effect agency operations. Substantive laws which are enacted to protect rights

https://doi.org/10.1007/978-3-319-70488-3

demand equal protection in administrative law as well as other areas of law (DOL 2018).

Federal Administrative Procedure Act (5 U.S.C. Subchapter II) (APA): The *APA*, officially enacted on June 11, 1946, is a US federal law that governs the way in which administrative agencies (positioned within the US federal government) may propose and subsequently establish regulations (APA 2018).

Model Administrative Procedure Act (Model State APA): The similar Model State APA was drafted by the National Conference of Commissioners on Uniform State Laws for oversight of state agencies. Not all states have adopted the model law wholesale. By comparison, the federal APA does not require systematic oversight of regulations prior to adoption as suggested by the Model APA (Oversight 2007).

Primary Types of Rules

The primary types of administrative rules are substantive rules that implement the intent of a law or statute, interpretive rules that provide explanation of law or action, and procedural rules that set forth procedures of an agency (Types of Rules 2018). The daily journal of the US government, the *Federal Register*, includes current issuances of documents from agencies, notices, presidential documents, proposed rules, and rules (Federal Register 2018). Regulations are first published in the *Federal Register* and then later appear in the Code of Federal Regulations (CFR). States, territories, and protectorates may have varying definitions relevant not just to administrative law generally but specifically regarding rules and their publication, and their availability in codes, manuals, and registers will also vary (Admin Rules 2018).

Agency Powers

What constitutes an agency is mandated by a legislature; e.g., § 551 of the APA defines each authority of the government of the United States but does not include the Congress, the courts of the United States, the governments of the territories or possessions of the United States, the government of the District of Columbia, and other exceptions (APA). An agency has diverse powers to set standards, make rules and regulations, take enforcement actions against those who refuse to obey the regulations, make decisions on those actions that come before it in claims and hearings, and investigate and take action regarding complaints on noncompliance with laws, agency rules, and regulations (APA).

Adjudication and Judicial Review

Administrative adjudication is the process by which an administrative agency issues an affirmative, negative, injunctive, or declaratory order. The formal proceedings before an administrative agency adopt the process of rule-making or adjudication (Administrative Adjudication 2018).

Judicial review is a process by which a court of law decides on the appropriateness of an agency's action in an appeal on the action. However, if there is a statutory prohibition on judicial review, the agency action is based on the agency's discretion. Some states create statutes that prohibit judicial review in administrative actions (Preclusion 2018).

The Administrative Procedure Act provides for comprehensive judicial review of agency actions. Any person adversely affected or aggrieved by agency action is entitled to judicial review as long as the action is a final agency action for which there is no other adequate remedy in a court (Yeboah 2001). The three criteria by which courts consider while deciding whether action of an agency is reviewable are as follows:

- The agency must have broad discretionary powers.
- Courts have to consider whether the action implicates any political, military, economic, or other choices not essentially legal in nature and, thus, whether the action is not readily susceptible to judicial review.
- Even actions committed to agency discretion by law are reviewable on grounds that the agency lacked jurisdiction, decision of the

agency resulted from impermissible influences, or such decision violates any constitutional, statutory, or regulatory command (Yeboah 2001).

In judicial review procedures, *Chevron* deference is a principle of administrative law requiring courts to defer to interpretations of statutes made by those government agencies charged with enforcing them, unless such interpretations are unreasonable. The principle is named for the 1984 Supreme Court case Chevron USA, Inc. vs. Natural Resources Defense Council, Inc. which involved a dispute over the Environmental Protection Agency's interpretation of a provision of the Clean Air Act Amendments of 1977 (Chevron 1984). Under *Chevron*, even if a court finds that another interpretation is reasonable, or even better than the agency's interpretation, it must defer to the agency's reasonable interpretation (Chevron 1984).

Conclusion

Administrative law is important to security and emergency management because both of those overlapping fields operate under laws that govern the creation and operation of administrative agencies. In order to understand how those agencies work, you must appreciate the creation, promulgation, enforcement, and appeal of rules, procedures, and principles created by government agencies and departments.

Specialized law consisting of *compacts, statutes*, and *policies* governs the intersection of security management and emergency management.

Introduction

Specialized law affects everyone who works in the fields of security and emergency management. This entry summarizes some of the most significant prescriptions and proscriptions needed for routine day-to-day operations and emergency operations of security management and emergency management agencies which rely upon authorizations and appropriations to accomplish core missions. In the next section, some of the most important and commonly applied laws in those realms, laws that provide the basis for compacts between governments and private entities, as well as overarching policies for the way ahead, are described.

Laws (ASTHO 2018)

Routine day-to-day operations, emergency operations of security management as well as emergency management agencies rely upon authorizations and appropriations to accomplish core missions, e.g. preventing terrorism and enhancing security, securing and managing borders, enforcing and administering laws, safeguarding and securing cyberspace, and ensuring resilience to disasters, both natural and man-made (Homeland Security 2016). What follows is a selection of some of the most important and commonly applied laws in those realms and which laws also provide the basis for compacts between governments and private entities, as well as overarching policies for the way ahead.

The Emergency Management Assistance Compact (EMAC) is a congressionally authorized interstate mutual aid compact that provides a mechanism through which states can provide assistance to other states during emergencies. All states have joined EMAC by adopting model language into their state's statutes. EMAC addresses reimbursement, liability, compensation, and licensure issues (EMAC).

The Federal Employees Compensation Act (FECA) provides workers' compensation to civilian federal employees who are injured or killed during the course of their duties. Volunteers who may deploy in states under federal programs like the National Disaster Medical System or are otherwise deemed to be federal employees are covered under FECA (FECA).

The Federal Tort Claims Act (FTCA) permits lawsuits to be brought against federal government employees in certain circumstances. FTCA allows individuals to seek compensation when they are injured by federal employees acting within the scope of their duties. The act immunizes federal government employees from tort liability (except in certain instances); the federal government assumes an employee's role as defendant in a lawsuit against the employee. Volunteers of federal agencies deployed by those agencies are entitled to coverage under FTCA (FTCA).

The National Emergencies Act (NEA) allows the president to declare a national emergency, which triggers emergency authorities contained in other federal statutes. NEA does not contain any specific emergency authority on its own but relies on the emergency authorities in other statutes, such as the Public Health Service Act. President Obama used the NEA to declare the 2009 H1N1 influenza pandemic a national emergency.

A declaration under the NEA (or the Stafford Act) and a Section 318 public health emergency declaration are required before the HHS secretary can exercise Social Security Act Section 1135 waiver authority (NEA).

The OBIM or *Office of Biometric Identity Management* (*OBIM*), formerly US-VISIT, provides biometric identity services to DHS and its mission partners that advance informed decision-making by producing accurate, timely, and high-fidelity biometric identity information while protecting individuals' privacy and civil liberties (OBIM).

The Pandemic and All-Hazards Preparedness Act (PAHPA) addresses the organization of public health emergency preparedness and response activities and authorizes programs concerning medical surge capacity, the capacity of states and localities to prepare for and respond to public health emergencies, and the development of countermeasures to biological threats (the Biodefense Advanced Research and Development Authority [BARDA]). Many of the offices and programs within the Department of Health and Human Services (HHS) that state public health preparedness programs interact with on a daily basis were developed or refined through PAHPA, including the Office of the Assistant Secretary for Preparedness and Response, grant programs such as Public Health Emergency Preparedness (PHEP) grants, the Hospital Preparedness Program, and the Healthcare Facility Partnership Program. The act also focuses on the needs of at-risk populations in emergency planning and response. PAHPA was reauthorized in March 2013 in the Pandemic and All-Hazards Preparedness Reauthorization Act (PAHPA).

The Public Health Service Act Section 319 authorizes the HHS secretary to determine that a public health emergency exists, which triggers emergency powers that permit the federal government to assist state and local governments, suspend or modify certain legal requirements, and expend available funds to address public health emergencies. A Section 319 public health emergency declaration is separate and distinct from a presidential declaration under the National Emergencies Act or the Stafford Act. The secretary does not need a presidential declaration to issue a public health emergency declaration under Section 319; however, a presidential declaration is required in addition to a Section 319 declaration if the secretary wants to exercise waiver authority under Social Security Act Section 1135. Other sections of the Public Health Service Act, including Sections 301 and 311, permit the secretary to render assistance to states and localities without declaring a public health emergency (PHSA).

The Public Readiness and Emergency Preparedness Act (PREP Act) authorizes the HHS secretary to issue a declaration that provides immunity from tort liability for claims of loss caused by countermeasures against diseases or other threats of public health emergencies. The act covers persons and entities involved in the manufacture, testing, distribution, administration, and use of covered countermeasures. A PREP Act declaration is different from and independent of other federal emergency declarations. A separate emergency declaration under Public Health Service Act Section 319 or another statute is not required for PREP Act immunities take effect (PREP Act).

The REAL ID Act, passed by Congress in 2005, enacted the 9/11 Commission's recommendation that the federal government "set standards for the issuance of sources of identification, such as driver's licenses." The purposes covered by the Act are accessing federal facilities, entering nuclear power plants, and boarding federally regulated commercial aircraft (REAL ID).

The Robert T. Stafford Disaster Relief and Emergency Assistance Act (Stafford Act) authorizes the delivery of federal emergency technical, financial, logistical, and other assistance to states and localities. A governor must first determine that an event overwhelms the state's capacity to respond and request a presidential declaration under the Stafford Act before the president can declare all or a portion of a state a "major disaster" or "emergency" area. The Federal Emergency Management Agency (FEMA) coordinates administration of disaster relief resources and assistance to states. The President can declare an emergency without first receiving a gubernatorial

request if the emergency involves an area of federal primary responsibility such as a federal building. A Stafford Act declaration can be used to trigger other public health emergency response authorities such as Social Security Act Section 1135 waiver authorities (Stafford Act).

The SAFETY Act, as part of the Homeland Security Act of 2002, Public Law 107-296, Congress enacted the Support Anti-Terrorism by Fostering Effective Technologies Act (*SAFETY Act*) of 2002. The *SAFETY Act* provides incentives for the development and deployment of anti-terrorism technologies by creating systems of risk and litigation management (SAFETY Act).

The Social Security Act Section 1135 authorizes the HHS secretary to temporarily waive or modify certain Medicare, Medicaid, Children's Health Insurance Program (CHIP), and Health Insurance Portability and Accountability Act (HIPAA) requirements affecting healthcare facilities and providers during national emergencies. Section 1135 waivers require both a presidential declaration under the National Emergencies Act or Stafford Act and a public health emergency determination by the HHS secretary under Public Health Service Act Section 319. Once the 1135 waiver authority has been issued, individual providers' requirements are not automatically modified; the waivers are implemented on a case-by-case basis through the Centers for Medicare and Medicaid Services, HHS regional offices, and state health facility survey agencies (SSA).

The Volunteer Protection Act of 1997 provides immunity from ordinary negligence to volunteers of nonprofit organizations or governmental entities. It does not cover gross negligence, willful misconduct, recklessness, or acts committed by the volunteer while intoxicated or operating a motor vehicle. It does not cover organizational entities of any type or persons volunteering at private businesses. The act does not require a declared emergency for its protections to apply (VPA).

Policies

Homeland Security Presidential Directives (HSPDs) and Presidential Policy Directives (PPDs) announce executive policies regarding, among other things, homeland security issues. HSPDs and PPDs establish policies, strategies, and frameworks directing executive agency activities on a range of homeland security matters. Directives important for public health are HSPD-5 (management of domestic incidents), PPD-8 (national preparedness – formerly HSPD-8), and HSPD-21 (public health and medical preparedness) (HSPD).

The National Incident Management System (NIMS) is a system of incident command developed by the Department of Homeland Security to coordinate emergency response efforts at all levels of government and the private sector. It is a scalable system that can be used for events and incidents of all sizes regardless of whether a federal emergency or disaster is declared under the Stafford Act (NIMS).

The National Response Framework (NRF) is a Department of Homeland Security policy document that uses a national, all-hazards approach to describe and integrate roles for governments at all levels and the private sector in preparing, responding, and recovering from emergencies of all sizes, regardless of whether an emergency is declared. The NRF uses NIMS to coordinate response activities. The NRF includes 15 Emergency Support Function (ESF) supplemental documents that detail the roles and responsibilities of governmental and certain private sector capacities in key areas. Relevant to public health are ESF-8 (public health and medical services) and ESF-6 (mass care, emergency assistance, housing, and human services) (NRF).

National Strategy Documents arise from federal legislation and directives that mandate the creation of various strategies and plans to chart national emergency planning and response activities. These national strategy documents are intended to complement the National Response Framework and address plans for coordinating with state, local, territorial, and tribal governments and the private sector. Relevant national strategy documents for public health include the National Health Security Strategy, the National Strategy for Pandemic Influenza, and the National Strategy for Homeland Security (NSD).

Conclusion

The enumerated specialized laws, consisting of *compacts*, *statutes*, and *policies* govern the intersection of security management and emergency management, affecting not only the governance of government agencies and departments but how they render security management and emergency management services.

Machine learning (ML) describes a wide array of algorithms that analyze data and enable a computer to make predictions.

Introduction

Machine learning (ML) describes a wide array of algorithms that analyze data and enable a computer to make predictions. Differing from traditional statistical analysis, which makes various assumptions about data, algorithms identified as machine learning typically let the data do the talking. ML at this point is coming to mean just about any automated system that learns from data, or which was created by learning from a data set, a so-called training set, and then used to make predications based on data not seen previously. Unlike a static program that takes data in and outputs an answer, a program using ML techniques takes data as input and based on the data can modify itself to be more effective at making predications and achieving its objective. Increasingly, ML techniques are used in some part of the automated systems with which users interact, for example, a natural language interface relies on ML techniques. Already many devices utilize ML algorithms and operate independently, self-driving vehicles being one such example.

Users are exposed to ML algorithms every day, for example, when they access any web site that makes recommendations or when they receive targeted ads. Indeed, many of the algorithms today classified as ML algorithms including search engines have been around for quite some time. More recent applications include facial recognition, medical diagnosis, fraud detection, and spam detection. ML plays a key role in robotics, for example, allowing computers to identify objects. Classification, based on test data (supervised learning) or without prior data (unsupervised learning), is an important subfield of ML. Such algorithms often play a prominent role in determining who is a credit risk, who gets paroled or who gets the job.

Several advances in computing have allowed the ML community to flourish in recent years. Certainly, increased computational power and storage, especially in small devices, has played a key role. The ability to design an algorithm that learns from data but keeps the code largely fixed

© Springer Nature Switzerland AG 2021

https://doi.org/10.1007/978-3-319-70488-3

in size has been very important as well. Expert systems had been around for years. However, these systems, which tried to incorporate expert knowledge, required code sizes to grow and become increasingly complex and unwieldly.

Many experts in the field point out ML techniques are often heuristic. In many problem areas, designers know how methods work on test data but cannot guarantee they will always perform as expected on data not seen previously. Despite impressive successes, many in the field still describe ML as part science and part alchemy.

There are two key reasons for the widespread rise in interest in ML. First, it has enabled the development of smart devices that can respond to a variety of situations, even situations that have never occurred before. Second, in almost any field, too much data is being created too rapidly for humans to process them without some type of intelligent digital assistance. In the medical field, without such assistance, it is impossible for medical researchers to be aware of all the publications, clinical trials, and drug interactions that might impact their work.

As ML-based systems proliferate and reliance upon them increases, these systems will present significant privacy and security challenges. The remainder of this entry describes some of the privacy and security concerns surrounding ML-based systems. In many instances, ML-based systems will also provide the solutions.

Privacy Concerns

Although privacy in the Internet age has long been an issue, no one has determined how to reconcile privacy risks with the current business models that make Internet services available. Simply providing more user control of privacy settings is not working. A recent review of the privacy literature concludes "users are often unaware of the information they are sharing, unaware of how it can be used, and even in rare situations when they have full knowledge of the consequences of sharing, uncertain of their own preferences" (Acquisti et al. 2015, p. 513). The research examined also shows user privacy decisions are impacted by context, for example, users are more likely to release sensitive information to well-known sites such as Facebook rather than lesser known sites. In addition, users are easily influenced in privacy attitudes by small rewards that can change privacy concerns. Users are quick to release data to gain a clear short-term benefit such as the use of an Internet-based service but prone to ignore the longer-term not so clearly defined risks of providing data or even just using the service.

On the other hand, when it comes to data collection, social media sites such as Facebook have a clearly defined purpose – collect as much data as possible and make every effort to monetize it. ML provides numerous opportunities to combine data from many sources to provide detailed profiles of people which are made available for sale. Not only data but full psychological profiles are now possible. Even detection and analysis of emotions are being considered with ML techniques (Gayo-Avello 2018). Increasingly, users cannot know the consequences of releasing data.

In his highly popular book, *The Master Algorithm*, Pedro Domingos describes a model for the future where the way users interact with the digital world is through a "digital half," essentially an ML-based program that presents users to the digital world and presents the digital world to them (Domingos 2015, p. 269). In many ways, this already is occurring, although not to the level anticipated in the book. The key question is who will control this technology and how will it be used. Right now, the motivation for providing such a service is advertising revenue. This front end, which people will rely on to access the digital world, will make decisions for them and know them intimately. It would likely incorporate current research that will allow the ML algorithm to gauge the mood of humans when using the system. One of the concerns is that users may not even be able to participate effectively in twenty-first century economic and social activities without such a front end or digital half.

Security Concerns

Although often portrayed as conflicting goals, without privacy there is no security. A fundamental tenet of security is the "need to know." It is usually

applied to classified information but is widely used by organizations and individuals to limit the damage done from the release of information, particularly by insiders. Aleksandr Kogan is a Cambridge University researcher hired by Cambridge Analytical to harvest data from tens of millions of Facebook profiles, data which was later used in the 2016 election without user consent. In an interview on April 23, 2018, Kogan, who had a long-standing relationship with Facebook, commented that the Facebook app can transfer and sell user data for up to year and half without notification from Facebook. He went on to say that social media platforms cannot be relied upon to police their sites, even if developers violate their policies. The basic business models of Internet companies create extreme incentives to share data with developers and advertisers, not to limit who has access to data nor to police privacy policies. Certainly, current business models, where users give away rights to data and how it is used, would be intolerable in a world where a digital half is needed to access the digital world and interact with it on a user's behalf.

As would be expected, hackers are also taking advantage of ML. An important Internet security challenge is the social botnet (Ford 2016). Social bots are computers running algorithms that automatically produce content and are able to interact with humans or computers and imitate human behavior, the classic idea of what artificial intelligence means. Such algorithms frequently use a range of machine learning techniques to interpret natural language, respond to queries, and infiltrate other systems. By commandeering a large collection of social bots, attackers can have a significant presence in social media which they then can use for a variety of possibly malicious or at least disingenuous purposes (Ferrara et al. 2016). Such bots may be used to artificially inflate support for a political candidate or to denigrate a candidate. Misinformation gains credibility by the mere fact that the collection of social bots appears to be individuals expressing an opinion or shared belief. Such bots have also played a role in click fraud and classic pump and dump schemes to inflate the value of stocks. ML algorithms make it much harder to determine whether users are bots or humans.

On the other hand, ML techniques are a key technology used to detect social bots. A bot that can change its behavior to adapt to its environment is hard to detect with standard algorithms. ML algorithms focus on general behavioral patterns to detect these bots. Rather than have an expert system try to predict all types of behavior, these programs are able to learn the behavior of a wide range of bots and then determine what computer is a bot and which one is a legitimate user (Davis et al. 2016). Stanford University now offers a course in ML-based bot detection. On the other hand, at Black Hat conferences, speakers discuss techniques on how to avoid ML-based bot detection. The age where security depends on an ML arms race may have arrived.

Increasingly, Americans are getting news from social media sites. A recent Pew Research Center report indicates that about 67% of US adults get some news from social media sites, up from about 62% in 2016 (Pew Research Center 2017). The report also states that Facebook is by far the largest social media news source with over 45% of US adults getting news from this site.

Social media sites rely heavily on machine learning algorithms to determine user preferences and interests. The sites provide news feeds and other news items that reflect those preferences. Many people claim this results in an increasing level of polarization and isolation of users as they predominantly receive news items that fit their profile and current notions (Lynch 2016). Those trying to influence political and social onions have a receptive audience for stories that support or harden a political position or social view. Some authors refer to this as a "filter bubble," since users are shielded from information that they do not like even if it is relevant to the discussion (Kelly 2016, p. 170).

Despite widespread belief in the value of disintermediation (i.e., no editors and anyone can post anything), social media sites now find themselves in the unenviable position of having to monitor content to filter out, among other things, violent extremist views, hate speech, pornographic material, and fake news. Again, machine learning algorithms are the way to examine the massive amount of content that is posted daily on social media sites. Blocking and filtering, however, reflect the biases of those who chose the data to train the ML algorithms used.

According to a New York Times report, YouTube removed over 8 million videos in the first quarter of 2018, 80% of which were removed with no human intervention (Wakabayashi 2018). Using ML techniques, social media sites, which for most Internet users provide a window to the information on the Web, are becoming content sensors for a large portion of the world's population.

Conclusion

In the foreseeable future, human lives will be dominated by automated systems which use a variety of ML algorithms. Users will most likely need some type of digital half to access and interact with the digital world. Users, however, cannot know the risks to privacy and security with the current state of digital world. What happens in an ML-driven world where users interact with algorithms that can practically imitate human behavior? ML offers incredible capabilities to take advantage of data, improve services, and gain knowledge. For Internet users, the benefits and risks will depend largely upon who controls these ML-based systems and how they are used.

Definition

Acceptable risks in maritime security are those that are determined to be residual risk after risk treatments have been implemented or have been

accepted after a rigorous and defensible security risk assessment has been conducted. Acceptable risks fall within the risk owner's risk tolerance.

Introduction

The maritime domain is a diverse and complex, multinational environment that does not easily lend itself to universally acceptable risks. Therefore, the key to understanding risk management and the determination of acceptable risks in the maritime domain is to understand the unique features of the maritime domain as well as key considerations in determining acceptable risks in maritime security. This entry provides an overview of the maritime domain and its unique characteristics, introduces the concept of security risk and its components, and identifies the concepts of risk tolerance and treatment as key elements in the determination and management of acceptable risks. Finally, the entry summarizes the challenges and unique considerations required to determine acceptable security risk within the maritime operating environment.

The Maritime Domain

In order to determine acceptable maritime security risks, the unique characteristics of the global maritime domain must be highlighted to provide an adequate context for the determination of acceptable risk. The maritime domain is fully reflective of the increased globalization of international trade as it transcends conventional understandings of legal jurisdictions and territory (Sakhuja 2010).

The maritime domain is characterized by six important factors. First, vessels and ports are increasingly multinational in nature. For example, it is not uncommon for a ship to be flagged in one country, owned or managed in another country, and crewed by persons from several other countries with no citizen of the flag state actually on the vessel. Additionally, ports may be operated by multinational operators in exchange for concessions that allow for a high degree of autonomous operations (Edgerton 2013).

Second, the global maritime environment is international as well as multinational in nature. By virtue of the nature of international trade, which is overwhelmingly transported by sea, the maritime operating environment is international. Vessels travel across international boundaries, as well as between continents in conducting their business. This has the effect of making the security conditions on ships, as well in all ports in a ship's voyage, a potential risk consideration for other countries. For example, if a ship transits from Indonesia to a US port via South Africa, the security conditions in both the Indonesian and South African ports are of interest to US authorities.

Third, as most of the world's oceans do not belong to any state, these are considered to be ungoverned spaces. These large swaths of the Earth's surface are under no country's jurisdiction which can serve to complicate security and enforcement activity. With the exception of Antarctica, and the aviation sector, this unique situation can make risk assessment challenging as legal authorities and jurisdictions are often unclear.

Fourth, maritime security is not easily pigeonholed into one isolated category, instead it is considered intersectoral. The maritime domain intersects with the broader transportation sector, especially where there are vital intermodal connections with roads and railways at seaports. Further, there is a strong interconnection with the energy sector as many oil and gas faculties are also ports where tankers load and unload cargo in addition to the large presence of off-shore oil and gas production facilities (United States Government 2007).

Fifth, and perhaps most importantly, the maritime operating environment is inexorably connected to, and part of, the global supply chain (World Bank 2009). Since most of the goods transported around the world are borne by ships and loaded and unloaded at seaports, any long-term or large-scale disruption of international shipping would have an extremely deleterious effect on world trade.

Sixth, the maritime industry is data-intensive, with millions of shipments and associated financial transactions underway at any given day,

coupled with the increase in reliance on digital systems to transfer and store information. In particular, the data includes contracts, banking information, personal information for employees and access control, container contents and security seal numbers, and other key information across the globe. Consequently, the data within the maritime industry is of potentially high value to those persons with nefarious intent, such as criminals and terrorists (Ahokas and Kiiski 2017).

Components of Risk

In determining acceptable risk in maritime security, the components to be assessed must be identified. While there are several accepted standards that provide guidance in the assessment of risk and provide definitions of the component, a basic and sound approach to *security* risk is use of the following formula (Fig. 1). The idea is that risk is perceived as the combination of threat, vulnerability, and impact.

As shown in Fig. 1, threat is the understanding of *who* potentially intends to carry out a harmful act. Vulnerability is the determination of *how easy or hard* it is to carry out a harmful act. Impact is an assessment of *what the results* of the harmful impact would be and how severe the results would be.

There are also a number for definitions of risk, but for the purposes of security, risk is the potential for unwanted or harmful events to occur (Bichou 2008). These definitions and components are specific to security and different from other risk approaches where risk may be considered a neutral state. For security professionals, risk is inherently negative.

Maritime Security: Acceptable Risks, Fig. 1 "Risk components"

Assessing Risk

Assessing risk involves putting a relative value to the risks identified and prioritizing those risks in a risk register. This process requires the participation of a fairly wide variety of stakeholders to include, at a minimum, security officials, industry experts, facility and vessel owners, and operators. Before the overall risk is assessed and determined, the individual components of risk must be assessed against the identified scenarios.

The following are general approaches to assessing each risk component – threats, vulnerability, and impact (Edgerton 2013). Threats are assessed by determining the intent, capability, history, and targeting of the actor or group. Threats must also be assessed in the context of the security environment. If the security environment is robust and effective, the threat may be lessened. Conversely, if the security environment is permissive and corrupt or ineffective, the threat may be greater.

Vulnerability can be assessed through a thorough review of the security measures in place. Further, vulnerability assessments may be aided by the execution of adversary pathway assessments whereby the potential routes and methods of the adversary combined with a knowledge of the potential methods and objectives that may be employed by the threat actors are used to determine the weaknesses in existing security measures.

Finally, assessing impact requires a nuanced understanding of not only the physical and near-term consequences of an adverse event but an assessment of the potential greater impacts including regional, national, and international security, economic impacts, and health and safety impacts. This assessment requires the participation of experts from many disciplines outside of the security profession.

The assessment of each component can be quantified against established standards of measure as desired in order to provide the ability to prioritize them.

Risk Tolerance

In order to determine the acceptable risks to maritime security, the risk tolerance of the

organization which has been assessed must be determined before proper treatment actions can be implemented (Institute of Risk Management n.d.). Every organization, whether it is a governmental organization or a private sector owner or operator of an element of the maritime environment, has its own level of risk tolerance. Some organizations are willing to tolerate higher risks in order to maximize efficiency or revenue while others are fundamentally risk averse. For example, seaport management teams may have widely divergent levels of risk tolerance. One seaport may consider a certain level of cargo theft and pilferage to be an acceptable "cost of doing business," while another may be much less tolerant of such activity.

In many cases, organizations have not undergone an attempt to formally determine or document their risk tolerance at the enterprise level (Risk and Insurance Management Society 2017). Possible reasons include:

- The organization determines risk tolerance in an ad hoc manner through deliberations with senior and middle management.
- The formal process of determining risk tolerance can be extremely uncomfortable as most people would prefer to not have to determine how much disruption or damage, their organization can withstand.
- There is often a reluctance to document risk tolerance as it then becomes potentially discoverable in litigation.

However, in order to determine acceptable risk levels, a formal risk tolerance exercise should be undertaken.

A key component that can inform the level of risk that an organization is willing to accept, can include a Business Impact Analysis (BIA) study and any associated business continuity and recovery planning. The findings of a BIA and recovery and continuity plans, however, often include information that is important to the determination of acceptable risk (*ISO/TS 22317:*2015*; Societal Security* 2015*)*. This key information includes two types of objectives. First, recovery time objectives refers to how fast key functions must be restored before unacceptable impacts are realized. Recovery point objectives, in contrast, refer to what level key functions must be restored in order to maintain an acceptable level of operations. Additional factors to be considered in determining risk tolerance include the level and adequacy of insurance that the organization has, the ability to shift operations to other locations or vendors, and the culture of the organization.

Treating Risk

Risk treatment is the process of determining how security risks should be addressed based on the risk tolerances identified and the assessed severity of the risk. Risk treatment is the activities to be undertaken to manage risk once that risk has been identified and assessed (*ISO 31000:*2018*; Risk management – Guidelines* 2018).

Once maritime risk has been assessed and prioritized and the level acceptable risk unique to a specific organization or company has been determined, risk treatment options are considered in order to bring risk to acceptable levels. While *risk mitigation* is often used in terms of addressing risk, there are actually four risk treatment options, which can be implemented separately or combined as appropriate.

The selection of the appropriate treatment option is directly relevant to the level of acceptable risk that has been determined. Risk acceptance is at the first level in which the risk does not require any treatment and can remain as assessed. The risk falls within the parameter of risk tolerance that has been determined. Risk avoidance is at the second level in which the risk is either sufficiently serious with no effective way to reduce it or would only provide such a minimal benefit to the organization that the seriousness of the risk outweighs any benefits. In this case, the risk may be avoided. Risk transfer is at the third level such that the risk has been assessed, but the most effective way to address the risk is to transfer the risk to another entity. Insurance is often cited as the most common instrument for transferring risk. Risk reduction is at the fourth level and means that the risk is reduced (in some cases,

eliminated) to a level that is acceptable to management. Once the risk has been reduced to a level assessed to be *As Low as Reasonably Acceptable (ALARP),* additional risk treatment can be applied. In some cases, the remaining, or residual risk, can be transferred. Otherwise, it is accepted.

Risk in the Context of Maritime Security

Maritime security encompasses a number of interrelated concerns, threats, and disciplines (Bichou 2008). These include:

- Maritime terrorism targeting ships and ports.
- Supply chain security in which cargo being transported by sea is susceptible to exploitation by criminal or terrorist groups.
- Smuggling of persons and contraband by vessels or via cargo.
- Cargo theft and pilferage.
- High-jacking and kidnapping.
- Piracy and armed robbery at sea.

Each of these threats require potentially different solutions that range from international governance structures such as treaties and codes, to enhanced maritime domain awareness through technology, naval, and coast guard forces, and command and control, to the development of commercial programs to incentivize good security management in the private sector.

Identifying Acceptable Risks in Maritime Security

There is no globally accepted list of acceptable risks in maritime security because the issue of maritime security is so complex and global in nature that there cannot be one approach to assessing and managing the acceptable risks to maritime security. Determining acceptable risks and the appropriate treatments is the function of a deliberate and defensible process of risk identification, assessment, and treatment based on the risk tolerance of the organization carrying out the assessment, whether it is a government or a private sector business. Further, the level of acceptable risks varies among public organizations and commercial entities, whose goals and objectives may not be aligned. Additionally, organizational culture and the maturity of management in assessing and addressing risk are contributing factors in the determination of acceptable risk in maritime security.

Conclusion

Identifying and managing acceptable risks in the maritime industry is a multidisciplinary activity that requires input from experts in maritime affairs, security, law, supply chain, economics, trade, and insurance. Determining acceptable risks will vary among organizations based on their culture as well as the results of other factors such as their ability to recover quickly or divert operations to other ports, ships, or locations. For governments, the determination of acceptable risks may also be driven by national and international politics and perceptions.

In maritime security, the primary considerations for the determination of acceptable risk hinge on the results of the assessment process informed by a broad spectrum of stakeholders. Due to the complexity of the maritime domain, it is impossible to clearly define specific criteria that are universally accepted in determining an acceptable level of risk. Therefore, the most advantageous approach to determining acceptable risk is through a well-defined and defensible process of risk assessment and treatment.

Definition

Armed private security guards aboard ships protect ships and their crews against pirate attacks at sea by using nonlethal and lethal force.

Introduction

Armed private security guards on board of ships for protection against piracy have a long history. It dates back to Ancient Greece when hired groups of mariners were tasked by city-states to capture and hand over ship crews of enemy forces but also share captured booty (Ormerod 1997: 34). During the age of colonization, in particular in the sixteenth and seventeenth centuries, naval wars between rivaling colonizing European countries peaked. Governments made use of privateers (or buccaneers), which was actually a sort of licensed piracy since these privateers held a "letter of marque" from a sovereign nation to attack the sovereign's enemies (Renwick and Abbott 1999). They were considered maritime mercenaries that had their own vessel, hired and fighting for their respective governments for financial gain. The use of privateers came to a halt when governments started to use their own professional navies instead in the eighteenth and nineteenth centuries when nationalization and the building of nation-states in

Europe set in. Fast-forwarding two centuries, piracy is still and even more aggressively prevalent due to various socioeconomic problems faced by impoverished nations, such as and in particular Somalia. The Somali people endured severe drought as a result of climate change, heavy losses due to illegal fishing by foreign ships, illegal waste dumping in Somali waters, political corruption, and (ethnic) conflicts; in order to survive, there seems no other way than to generate "booty" through piracy (Beri 2011). As a response, Private Maritime Security Companies (PMSCs) entered the market, seemingly fulfilling a similar role as the privateers centuries ago. They operate not necessarily in assistance of their nations waging naval wars but rather in the protection of global shipping companies and their ships and crews against maritime terrorism and armed robbery and especially against modern piracy. This entry shall focus on the effects of PMSCs and their weaponized security guards onboard of ships against modern piracy.

Privatization and the Approach to Modern Piracy

Private Maritime Security Companies (PMSCs) are a result of the neoliberal governance mode in which the government acts from a distance as a minimalist state and lets the market fill in the governance gaps. Key for that type of governance is deregulation and privatization that restructured welfare states across the globe, letting public services be taken over by private parties as the market would function more efficiently and cost-effectively (Larner 2000).

In the maritime domain, a similar pattern has emerged. Most nations started using armed guards when governments became aware that it is not cost-effective anymore to provide their own navies (Jeffrey 2010). Simultaneously, insurance companies became more and more hesitant to pay ransom money to pirates that merely had to demonstrate that they were capable (without actually having to do it) of hijacking ships, kidnaping crews, and stealing cargo. Consequently, more responsibility was required from shipping companies in order to be eligible for being covered, and thus PMSCs are cheap solutions; however, "[r]esistance from the insurance industry is [still], however, potentially one of the primary obstacles to vessel self defense" (ibid. 512).

When PMSCs are deployed to offer protection, it occurs predominantly and most well-known, in the form of having a much cheaper group of armed private security guards on deck instead of more expensive naval forces escorting ships and ship crews through piracy-prone areas. The main difference between PMSCs and Private Military Companies (PMCs), as well as Private Security Companies (PSCs), is that PMSCs are principally sea-based and the other two mostly land-based. Still, although the sea has its unique characteristics and specific challenges, it is difficult to apply this dichotomy to all private actors in the field of maritime security, because counterpiracy can also be undertaken on land (Liss and Schneider 2015). The International Maritime Organization (IMO) speaks in terms of Privately Contracted Armed Security Personnel (PCASP), which seems to overcome that dichotomy.

Along with the privatization of public services, including protection by the state, the rise of modern piracy in the Gulf of Aden and off the Somali coastline in the early 2000s and the more recently rise of piracy-prone areas in Southeast Asia and the greater Gulf of Guinea have led to increasing costs for the shipping companies and security of their fleet at sea, turning piracy risks into high primary and secondary insurance expenses. In fact, it seems to be the case that, because of the increasing growth of piracy-prone areas, the use of PMSCs has risen drastically and heightened the competition between private maritime security providers. Consequently, that rise may have led to the fall of prices of PMSC employment; it pushes PMSCs, in order to keep a profitable business, to offer cheaper counterpiracy solutions, which could affect the quality of armed guard protection on board ships (Mudrić 2011).

It is up to flag-states to decide whether armed guards are allowed aboard their vessels or not, for which clear policies must be given, as recommended by the IMO. Given the claim that no armed ship has been taken captive by pirates, flag-states and shipping companies (as well as the

International Union of Maritime Insurance (IUMI)) are more willing to accept and have armed guards on board of ships than before. It is actually because of that claim that having armed guards on board could function solely as a preventative measure (Pizor 2012). Meaning, armed guard firing shots are actually not the main objective; their presence is enough of a deterrent. Still, in order for armed private security guards to actually be able to use their guns while obeying the law of "the flagship country, territorial waters, and ports they travel through [. . .] countries have begun to change gun laws for both the flagships and territorial waters, recognizing the need for laws allowing armed guards to utilize the legal defense of self-defense" (ibid. 549). For example, it was not until Captain Richard Phillips was kidnapped in 2009 when the United States changed their laws finally to allow armed private security guards on American ships.

Nonlethality and Trust

It is often forgotten that the actual use of fire arms by armed private security guards is usually an "ultimum remedium," a last resort, to establish robust counterpiracy measures on board. If only because using "guns may not always be necessary, particularly in incidences in which local fishermen simply approach the protected vessel out of curiosity without any malicious intent" (Liss 2007: 162). Using private security armed guard teams has become the standard solution as they assist in implementing and carrying out most of the other, unarmed, and nonlethal counterpiracy solutions based on the Best Management Practices for Protection against Somalia Based Piracy (BMP4 2011), which is one of the most important "soft law" solutions in counterpiracy practices. Also, they replace the need for having special security equipment on deck, crew counterpiracy training, armed convoys, military personnel on deck, or having to make alternative thus longer routes that altogether are not as cost-effective as having armed guards (Mudrić 2011). Furthermore, armed security guards may assist (also in ports) to prevent stowaways from entering vessels, from cargo and container theft, from drug and arms trafficking, and from terrorist attacks against ship crews (Eski 2016; Haywood and Spivak 2013).

When a team of armed guards, usually consisting of four up to five guards, is on deck, the BMP4 must be taken into account as well by that team itself. They assist the captain and ship crew in monitoring the surroundings when the ship enters a high-risk area. The physical barriers, such as razor wires and/or water cannons, are usually already put in place. The team divides itself up in certain positions, starboard and port side and back and front side. They patrol as well and also attempt to get acquainted with the crew members, if only because of instructions and giving security advice and training. The team leader and the captain and/or first officer (ought to) negotiate together what should happen in case of a piracy attack. Another important element that guarantees that armed guards are not excluded from the daily business and routines on deck is that the PMSCs are predominantly founded and staffed by ex-military or ex-law enforcement professionals (Liss 2007). The professionalism and combat experiences ease crews and give them confidence in making it through high-risk, piracy-prone areas without any harm inflicted on them. These steps of advising, negotiating, and assisting in setting up physical security effectuate that trust is created between the armed guard team and the ship crew, which is crucial in case a potentially lethal conflict situation may develop after all.

When "reasonable suspicion" arises that a ship is facing a piracy threat situation, the ship crew plus the armed guards ought to take specific recommended actions. These actions are divided in the approach stage and the attack stage (BMP4 2011). During these stages, the armed guards are not immediately allowed to engage in nonlethal, let alone lethal, firing of shots. Different nonlethal defense possibilities must be explored, such as maintaining maximum speed, following the emergency communication plan, providing ballistic protection to crew against pirates, and coursing away from approaching small boats, such as skiffs and/or so-called mother ships. In all of this, it must be absolutely sure that there are no clear visible signs of the crew being armed. The armed guards

must therefore not only be specialists in securing the perimeters but must also have expertise in identifying piracy and piratical "suspicious activity" (Symmons 2012).

Lethality, Accountability, and Profitability

If a small boat and/or a mother ship has been identified as a piracy vessel, and arms have been seen on board the vessel, it is usually based on agreements between the armed guard team leader and the captain what ought to happen in terms of firing nonlethal and lethal shots. Usually, the nearing pirates are addressed by an armed guard via a megaphone – when that does not work, warning shots are fired, and if that proves to be useless, the bow and subsequently the engine of the small boat are shot to neutralize the moving small vessel. If that does not stop the pirates, or they fireback directly at the ship and its crew, or it becomes clear an RPG rocket launcher is being prepared to fire at the ship, lethal use of force could be used by the armed guards against the small boat. Once more, also in highly dangerous, lethal situations, it is only after certain steps are taken that the armed guards may act, and also this detailed procedural process establishes trust between the captain, crew members, and the team itself.

It has happened that fishermen on skiffs have been mistaken for pirates, resulting in fishermen being wounded or even killed (Mudrić 2011). Many of these incidents seem to "remain unaccounted for, as they will most likely occur at sea and out of sight of authorities or witnesses [. . .] it is understood that if P[M]SC employees carry guns, they are also prepared to use them" (Liss 2007: 162). These incidents remain exceptional, and increasingly more attention is paid to international regulatory frameworks to control excesses of (wrongful) violence by armed private security guards, such as the International Code of Conduct for Private Security Service Providers (ICoC), several IMO Circulars, ISO 28007, as well as various nongovernmental initiatives (Liss and Schneider 2015). Still, it remains problematic that there are very limited possibilities to monitor PMSCs and deployed armed guards aboard ships who act on behalf of those PMSCs, which means that "the whole private [maritime] security system relies finally on single individuals' decisions, accountability, personality, training and performance" (Chapsos 2014: 194).

Conclusion

The existence of private actors having such availability to state-legitimized yet unchecked for coercive force seems to predominantly serve the interests of their own PMSC (comprising mostly of boosting profitability of the company) rather than those of the ship crews themselves. This perverse effect of the marketization of (maritime) security could reignite debates on (modern) privateering, as it was performed centuries ago (Gould 2017), with a focus on particularly the question of whether PMSCs are indeed as "cost-effective" if their deployment means innocent lives are taken. Those debates could be constructive for the construction of a more coherent, transnational set of collected "best (management) practices" for, in particular, education and training of private security guards in the maritime sector. Moreover, rethinking (modern) privateering could be helpful for codifying – and although problematized by the international community and maritime as well as security industries (Krahmann 2016) – specific international regulations governance of PMSCs.

Maritime Security: Contraband

John M. Jelenek

Keywords

Contraband · Coordination · Interdiction · ISPS Code · Public-private partnership

Definition

Maritime security in this context refers to the standardization and bolstering of efforts across agencies and governmental administrations to increase efficiency in the prevention of illicit smuggling activities and capturing illegal material before it makes land fall (International Maritime Organization/IMO 2019).

Introduction

In the pre- and post-9/11 years, US maritime and port security has taken a strong stance on the physical mitigation, prevention, and preparedness in regard to occurrences at seaports, arguably the most vital economic vein for the USA and the world. Despite millions of dollars having been invested in security operations at the various ports across the USA, known drug smuggling operations through maritime avenues have gone relatively unhindered. Two main reasons for this problem are a lack of coordination between public and private law enforcement personnel at the seaports and a nonexistent standard of training for

the private personnel that relies almost solely on recommendations (International Maritime Organization & International Labor Organization 2003). Efforts to address these issues included the passage of the Maritime Transportation Security Act, which effectively transferred control of US maritime security operations to the Department of Homeland Security and the Transportation Worker Identification Credential Program and Container Security Initiative, which bolstered the strong stance on protecting the homeland from seaborne terrorist attacks via CBRNE weapon usage (CBO 2016; CRS Report 2005; Leonard et al. 2015; Nemeth 2017b). However, detection, screening, and intelligence programs gauged toward the war on contraband have gone relatively unchanged since the late 1990s.

An active and consistent threat with significant impact seen across the USA is the use of cargo containers to smuggle illicit material through established maritime routes to seaports and onto US soil. Success in this type of operation by transcontinental criminal organizations is widespread as shipping hubs on all coasts are targets (CIA World Fact Book 2019). Being a worldwide phenomenon, drug smuggling is not limited to any sole group, and the demographics of the people involved will change depending on the region(s) in which the cargo is leaving and entering. The tactic of using and embedding illicit material within cargo containers was implemented in the 1990s and is still used due to three facts. First, screening methodologies focus almost solely on CBRNE threats (Nemeth 2017b). Second, financial loss due to slow processing has encouraged a pattern of rushed screening of containers; specifically, out of the near 12 million containers reaching the USA annually, roughly only 600,000, or 5%, are screened and searched (CBO 2016). Third, there is an evident lack of joint training and communication between the Customs and Border Protection (CBP), US Coast Guard, and their private law enforcement counterparts stationed at these ports. The only mention of cooperation is with foreign government agencies with a similar role (CBP 2019). There is no information on the training requirements for port security contractors beyond a list of courses provided by licensed training providers and the standards established by the US government through the National Maritime Transportation Security Plan (Cornell Legal Information Institute), leaving a relatively blank slate to reform and build off of current policies and directives in order to create a comprehensive and standardized training program with fluid communication between public and private law enforcement officers being paramount.

Offender Demographics and Methodology

In order to build a comprehensive policy not only applicable to the USA, but globally, this section will provide an overview of the demographics of offenders; current security procedures in place for mitigation and prevention; the private-public partnership, both in its triumphs and shortfalls; and areas in which improvements can be made. The reality of our interconnected world, which thrives on trade from all over the globe, is that groups in various locations and of various backgrounds are able to take advantage of this security void for their own devious operations. In the case of drug smuggling operations involving maritime methodologies, there are specific groups who have the most activity. Due to their proximity to the USA, people of Afro-Carib, Amerindian, and Hispanic descent from areas, such as Jamaica, Dominican Republic, Cuba, Mexico, Colombia, and Haiti, ranging in age from adolescence to late adulthood, are the most prevalent in smuggling marijuana, cocaine, and heroin to the Atlantic Coast (Department of Justice 2011, pp. 15 & 16; Department of Justice 2015, pp. 1–4; Department of Justice 2016, pp. 6, 10 & 14). This age gap depends on the length of time of the person's affiliation with the criminal organization and also reflects the reality that people of all ages will take part in these activities in order to support themselves or their families. For operations on the Pacific Coast, people of Asian descent are most often involved in smuggling (Department of Justice 2015, p. 6;

Department of Justice 2016, p. 16) and predominantly supply purified ecstasy, known as MDMA, and smaller amounts of crystal methamphetamine (Department of Justice 2015, p. 7). Fentanyl, a highly toxic synthetic opioid, and its precursor chemicals have also joined the list in the past several years. In regard to the age of perpetrators of Asian descent, they also range in age.

The motives behind the offenses performed by those engaging in smuggling activities have been and are currently based completely in profitability. Drug trafficking, counterfeit goods, gun running, and human trafficking are ideal money-making opportunities for criminal organizations and illegal businesses, especially in a market as large as the USA. As of 2010, a White House report estimated nearly $109 billion was spent on narcotics in the USA alone; this number had gone virtually unchanged since a similar 2000 report (Business Insider 2016).

The main method in which illicit drugs enter the US homeland through maritime routes is through the commissioning of private vessels ranging from small outboard engine vessels to submarine-type craft to be used as runner boats. The idea is to move quickly, traveling from point to point without raising suspicion or drawing too much attention. This method, popularized by South American cartels such as the Sinaloa, has proven to be successful, but it does not directly involve major US seaports as drop zones are usually in discreet locations along the coastline of the Southern USA (Department of Justice 2017). Alternatively, cruise ships and ferries have also been utilized as another form of product transport, predominantly in southern Atlantic ports and in Gulf Coast ports. Lastly, commercial ships, specifically container transporting vessels, have become a key asset to transcontinental criminal organizations (Department of Justice 2010). The use of these benign behemoths is the newest and the most discreet mode of transport as copious amounts of the chosen payload can be stored among the immense number of cargo containers, among cargo and provisions deemed necessary for successful voyage, or among typical carry-on luggage of the personnel on board (IMO 2017). For operations involving cargo ships, the crew members are considered to be main smuggling suspects as many of the personnel, especially coming from South America, are usually involved with the trafficking organization. The increased favoring by smugglers for commercial container transports has been due to their size, known lack of screening, and, as stated before, ability to involve the crew of the vessel (Department of Justice 2011, pp. 15 & 16). As of 2009, the estimated worldwide total of shipping containers used yearly to transport over 90% of worldwide goods from point to point was approximately 420 million (UNODC 2009); however, the current estimated total of all shipping containers in the world sits at upwards of 35 million units (World Shipping Council 2017 & *Container Supply Review: May 2011* 2011, p. 3).

Security Procedures

It is a ceaseless task to secure US and global seaports alike as the cargo entering them each day and the list of procedures and stakeholders involved are constantly growing and changing. Following the creation of and consolidation of agencies under the Office and Department of Homeland Security in 2001, maritime operations became a necessary and costly, yet effective, investment. The same is to be said for the private sector involved in maritime operations. In fiscal year 2017, an estimated $2.3 billion of the total DHS budget went to marine operations (DHS 2017, pp. 4 & 5) involved with securing ports and the interdiction of drug and general smuggling personnel and paraphernalia.

Positive procedures for security and interdiction have developed from multiple national and international agencies and departments such as the US Customs and Border Protection's requirement and partnering with businesses to form standards of screening their shipping employees and personnel, listing of all parties involved with the contents of containers and cargo, and the thorough inspection of containers heading to US ports (CBP, Security Profile for Businesses & CBP 2009); the creation of the International Maritime Organization's ISPS, or International Ship and

Port Facility Security Code, in 2002 and its update in July 2014 to standardize and bolster current international risk management and security procedures (International Maritime Organization 2017 & International Maritime Security Organization 2017, FAQs); the US Coast Guard's training and development programs for container security and interdiction (Nemeth 2017b, pp. 421 & 422); and the United Nations Office on Drugs and Crime's Global Maritime Crime Programme, which helps to train law enforcement and military units throughout the world on tactics and procedures for capturing and preventing drug smuggling and terrorist activity at sea and at ports worldwide while also properly investigating and fully prosecuting these actors (UNODC 2016, pp. 4 & 5). US-born security implementations in conjunction with international standards and procedures create awareness throughout the world's governments and private sector organizations, fostering communication and cooperation while successfully apprehending suspects around in all bodies of water from the Atlantic Ocean to the Strait of Hormuz (Nemeth 2017b, p. 427; U.S. Coast Guard 2015; UNODC 2016, pp. 11–24).

Although there are positive procedures and initiatives that have proven to be effective, there are still those remaining which have done little to aid in the worldwide fight against maritime drug smuggling. The current training of those involved with large cargo or people-carrying ships, as well as ports, is lacking in many areas. Classroom-style training geared toward securing the port cannot substantially display the situations the port officers will find themselves in as they will become functional search units for containers that have been flagged. Combining a lack of training, restricted searches to flagged containers of interest, and an inability to screen the flagged containers and ships alike thoroughly within a set time frame can lead to an endless cycle of illicit items "slipping through the cracks."

Companies and stakeholders in general in the USA adhere to the 2002 Maritime Transportation Security Act and to the ISPS Code when in international waters, but there is little specificity or acknowledgment of training length for personnel involved in maritime security. The 46 US Code § 70125 simply outlines the topics that port security officers must be trained and proficient in as well as which companies are licensed to train; however, this goes without mention of a standardized training time frame (United States Government 2010). Companies ranging from Academi to DNVGL vary their training from a few days to a full week or more, presenting their courses in different manners for different maritime situations. This lack of congruency comes with the issues of security personnel being trained to varying proficiency levels in monitoring and response efforts for hostile situations or suspicious activity and in the proper methods of searching cargo containers for tampering or contraband presence (United States Government 2010).

Public and Private Stakeholders

The public agencies directly involved in the task of maritime and port security are the US Customs and Border Protection and the US Coast Guard as they directly make arrests, conduct searches and seizures, and ensure that ships, containers, and crew members are compliant with US code (Nemeth 2017b, p. 436). However, in the case of illicit drug smuggling, many other peripheral and cooperative agencies are also involved due to the landfall of copious amounts of these substances. The FBI, DEA, NYPD and their Regional Intelligence Center, and local law enforcement agencies (Department of Justice 2008) across the USA with jurisdiction in areas with seaports play crucial roles in intelligence acquisitions, investigations, and arrests in regard to the drug trade and the people involved.

Port security breaches in regard to drug smuggling and the responses elicited after a breach are few due to the nature of these breaches occurring often and without realization. The breach tends to be found once the substances have made it to their final destination and hit the street for distribution. There is no information on concrete response methods used by either sector (CBP 2017a, b). One can assume that following an apprehension and

investigation involving illicit drugs, information yielded about how the drugs arrived in the country would be dispersed to all other public agencies and then to the private companies providing security and screening operations at these ports. A tightening down of operations would be the logical response. One of the disheartening factors in this is that the National Incident Management System and Incident Command System, as well as their corresponding National Response Framework, are not used for drug intelligence and incident response (FEMA 2008, 2013). The only mitigation and coordination currently underway directly involving the private and public sectors are through interdiction and screening; screening has been the least effective as most programs initiated by the USA for global use focus on CBRNE threats at seaports, such as with the CBP's Container Security Initiative, the C-TPAT, Maritime Transportation System Security Plan, and the National Strategy for Maritime Security (Nemeth 2017a, pp. 377, 379, 419 & 421).

Coordination methods, as stated before, do not thoroughly deal with or mention drug trafficking and smuggling. Coast Guard interdictions at sea and law enforcement operations on land have yielded the highest removal of narcotics as well as the production of intelligence (Coast Guard Compass 2017) while also leaving the private sector virtually in the dark and in a state of proverbial business as usual. With an obvious lack in coordination methods for incident response and mitigation, likelihood of success by the actors only increases.

Opportunities for Improvement

The spotlight of maritime security procedures and technology development has been on the prevention of terrorism and possible attacks, creating a lack of focus on the illicit drug trade and its involvement of US and international seaports and waterways. Increased training, stricter requirements of new hires, increased coordination between private and public organizations, increased port security officer salaries, and better detection methods such as the use of drug-sniffing canine units are the most viable options fiscally and operationally that can be executed with relative ease (CBP 2019; IMO 2003).

Public agency-sponsored training has reflected a lack in drug indictment training for private sector members of security operations. The proof of this is in over 20,000 drug-related cases in which a majority was trafficking related, a substantial portion coming from maritime avenues of initial delivery (USSC 2015, p. 6). With the exception of the Coast Guard's boarding exercises and proficiency among its proprietary personnel, seaport practice events organized by the Coast Guard that also include private guard forces do not reference or deal with the finding of drugs and associated paraphernalia on personnel or within cargo containers (Nemeth 2017b, p. 430) and instead focus on explosive ordinance disposal and similar threats from unidentified and suspicious maritime and land vehicles (Book of Maritime Security Exercises, Appendix 5-1 through 5-4). Deficiencies are found across the board from access control measures to the requirements of drills (Nemeth 2017b, Fig. 10.34), an unacceptable reality that can be fixed with the use of knowledge through experience, information, and incentive. By increasing the information and intelligence flow to the private contracted personnel providing supplementary security and law enforcement at seaports, targeted containers and ships of interest can be held and their contents sifted through with supervised expertise. Agency-sponsored standardized training used to create congruency in the abilities of Coast Guard and port security officers will put the information to use in an efficient way and bolster the currently implemented Container Inspection Training and Assist Team (Nemeth 2017b, p. 432). Another inherent benefit to this is the utilization of the ability of probable cause of the security officers (United States v. Day; Nemeth 2017b, p. 434) to search these vessels and containers in question. While considered a legally questionable action by some, it can improve the ability to intercept illicit drugs before they hit the mainland by bypassing typical conduct and search and seizure legalities public law enforcement officers must adhere to.

With increased information, there potentially is a risk of issues in trustworthiness and

competence. Strong vetting procedures similar to that of the requirements to obtain a governmental secret clearance and increased standards for required education and experience help mitigate this problem (CBP 2019; IMO 2003). An established history of the candidate or current security officer will remove questionable personnel, and an education specializing in law enforcement, homeland security, or security operations makes them more attractive as a member of the public-private team.

The long fought and ongoing battle in the private security industry in regard to compensation cannot be avoided in this sector of operations. The US Department of Justice notes that coordination is essential to a successful drug smuggling operation and at times those who clear and handle cargo are on the payroll of a trafficking organization (Department of Justice 2015); this does not exclude security personnel. Although a broad representation over multiple focuses within the security industry, as of May 2016, the Bureau of Labor Statistics' (2017) data shows that the average security officer earns roughly $25,000 per year or $12 per hour. When compared to their Coast Guard counterparts, the disparity is noticeable as officers are paid at a GS-5 or higher pay grade and Specialists outearn both of these, doubling their salary. By improving pay, the desire to break the law in order to earn extra money is reduced, and quality of work and employee loyalty will rise.

Bolstering the human end of these operations, canine units and their superior natural detection through scent have proven invaluable through use by law enforcement worldwide. For seaport drug detection, the German shepherd breed would prove most useful as they have the highest average percent of detection of a range of drugs at around 80% (Jezierski et al. 2014). These animals have been widely used and have successfully located hidden drugs at land-based ports of entry, leading to arrests and seizures of illicit substances with monetary street value in the millions (CBP, Pharr Int'l 2017a; CBP, Laredo 2017b). By investing in the training of handlers and dogs, targeted containers and ships can be thoroughly swept beyond what a human can achieve. In addition to this, the ability to cover a larger area of the port and increased number of containers that may have not been flagged will boost operational efficiency. The cost of training, averaging at approximately $3,000 per dog and $5,000 per handler (Coutts, Cost of a Canine Program n.d.), plus necessities and upkeep, will have a guaranteed exponential return on the original investment when a small team is formed.

Conclusion

Through the increased training and coordination of public and private entities tasked with the security operations of maritime and seaport assets and the interdiction of illicit drugs, the assumed effect is that there will be a decrease in the quantity of these substances making their way to the global street market. By removing the accessibility to these substances, public health will increase as addiction rates and communicable diseases related to the paraphernalia used decline and mortality rates from drug overdoses decrease. In 2016, there were over 60,000 fatal drug overdoses in the USA alone; a 20% increase since 2015. It is estimated that nearly 21 million Americans have an illegal substance abuse problem (ASAM 2016; NIDA, Heroin 2017a; NIDA, Overdose Death Rates 2017b). As for security operations at seaports, standardized communication and training for the private and public organization personnel involved will lead to a well-rounded operation filling the vulnerabilities that were once commonplace, tightening down on what can be considered as acceptable risk, and establishing a standard that other nations can build and improve their own operation procedures upon.

Maritime Security: Problems of Security Versus Safety Practices

Yarin Eski
Knowledge Hub Security and Societal Resilience/Political Science and Public Administration, Vrije Universiteit Amsterdam, Amsterdam, The Netherlands

Keywords
Maritime safety · Maritime security · Resilience · ISPS Code · SOLAS

Definition

Overall, maritime safety encompasses the protection of ports, ships, and their communities against unintentional dangers and harms (e.g., storm at sea), whereas maritime security encompasses the protection of ports, ships, and their communities against deliberate dangers and harms (e.g., piracy). The two can be complementary or conflicting.

Introduction

The safety versus security debate is persistent in any professional domain, whether that is in agriculture, policing, education, or IT (Line et al. 2006), and thus in the maritime industry as well. Overall, "[t]he inability of the system to affect its environment in an undesirable way is usually called safety; the inability of the environment to affect the system in an undesirable way is usually called security" (ibid. 1). However, depending on the environments and systems themselves, as well as the damaging effects they can both have on each other, there can be numerous definitions of safety and security. The maritime safety versus security divide (if a divide at all) resembles the divide in other domains and is similar to the (definitional) issues that come along with it:

> Maritime safety accidents are unintentional, while maritime security and piracy incidents are intentional. Maritime and piracy incidents differ in that the focus of the forms is damage to property and/or injury to individuals for political reasons while that of the latter is theft. Maritime safety accidents, security incidents and piracy incidents, however, may have the same outcomes – injuries and property damage. (Talley 2013, p. 1)

For a long time, the focus of ships was predominantly on safety, given the daily concerns of being at sea (e.g., sea storms, ship damage, etc.), which changed drastically after 9/11 but not easily resolved, as security required almost the opposite acts and equipment to the need for safety.

In this entry, key issues in the maritime safety versus security debates, and where problems may arise, shall be explored by giving a concise overview of the International Convention for the *Safety* of Life at Sea (SOLAS) and the International Ship and Port Facility *Security* Code (ISPS Code). Furthermore, this entry explores the conceptual and practical ambiguity of maritime safety and security in the everyday of the maritime industry.

Maritime Safety: SOLAS

SOLAS is an immediate legislative response to the sinking of the Titanic in 1912. It came into force in 1914 and brought about new obligations for particular ships to comply with, such as a minimum number of lifeboats and obligated specific safety equipment (Eski and Carpenter 2013).

Ever since, SOLAS received many amendments, especially in the twentieth century. The Inter-Governmental Maritime Consultative Organization (IMCO), which has become the International Maritime Organization (IMO) since 1982, is the official body to deliver and update legislation for ships and ports to comply with SOLAS (ibid.). Several key topics are covered under maritime safety, including carriage of cargoes and containers, fire protection, navigation, radio communications and search and rescue, stability and subdivision, and the international and national safety regulations themselves (IMO 2018).

These days, the term "maritime safety culture" has gained popularity and is heavily promoted throughout the maritime industry by the IMO (Ek et al. 2014). The following is stated by the IMO on safety culture:

> An organization with a 'safety culture' is one that gives appropriate priority to safety and realizes that safety has to be managed like other areas of the business. For the shipping industry, it is in the professionalism of seafarers that the safety culture must take root. (IMO 2012)

There is, however, no homogenous maritime safety culture, because the professionalism that is required of maritime professionals in ports and on ships "is determined by attitudes and performance, very often shaped by the culture of the shipping company" (Ek et al. 2014, p. 180), and these can differ also in maritime security practices and culture.

Maritime Security: ISPS Code

A major amendment to SOLAS was the addition of a new Chapter "Special Measures to Enhance Maritime Security", following a Conference of Contracting Governments to the Convention that was held in London in December 2002. It was done so due to the Twin Towers attacks which amplified security awareness significantly in the maritime industry, requiring, predominantly:

> . . .the installation of automatic identification systems on ships, the need for security plans for ships, port facilities and off-shore terminals, the need to verify the identity of seafarers and the question of a secure 'chain of custody' for containers from their port of origin to their destination. (Von Hoesslin 2005, p. 1336)

Codifying the identified needs, the International Ship and Port Facility Security (ISPS) Code (IMO 2003) entered the maritime industry. It identifies and intensifies cooperation between a wide variety of public and private partners, ranging from the police to customs, to security companies and port authorities, all working together through multi-agency partnerships, in the name of "maritime security" to tackle, first and foremost, terrorism and maritime-related crime, such as drug trafficking, human smuggling, and cargo and container theft. The Code also aims to harmonize interpretation and implementation of SOLAS Chapter "Special Measures to Enhance Maritime Security", and the ISPS Code throughout the world, as well as enabling the cooperating public-private maritime security and policing institutions to share information with each other, nationally and internationally. The Code has brought major differences to the maritime industry, in particular in regard to physical security, turning the once open port territory to an international zone that is closed off from the main public. It also introduced new roles which ships and ports had to fulfill as of 1 July 2004.

The ISPS Code consists of a mandatory part A that lists security obligations which ships and ports must be in compliance with and a recommendatory part B, although the part B provisions are practically as mandatory as part A is (Kim and Lee 2013, p. 283). The ISPS Code aims to standardize the evaluation of security risks and to make sure that all ships and ports, in interaction with each other, "perceive and manage security threats through integrating local/domestic threat-levels into a global awareness-level" (Bichou 2004, p. 328). Still, there is room in the ISPS Code for variations in ship and port security settings (IMO 2003), as long as measures taken cause minimum interference to daily transport activities.

In line with standardization, new official security roles are mentioned that must be present (whereas official safety roles are not as clearly described), such as the ship security officer (SSO), the port (facility) security officer (P(F)SO), and a designated authority (DA). Moreover,

there are different official documents, such as the Declaration of Security (DoS) that is established between the SSO and PFSO, or the Ship Security Plan/Port Facility Security Plan (SSP/PFSP), and the Ship Security Assessment/Port Facility Security Assessment (SSA/PFSA) that must be designed and approved for each ship and facility. These roles and documents ought to guarantee continuous development of maritime security (harmonization) through the identification of (threats to) critical infrastructure and any weaknesses in the maritime industry.

Maritime Safety Versus Maritime Security: Conceptual and Practical Ambiguity

English is the maritime language, and thus, naturally, there is the complexity of different linguistic understandings of maritime security and safety (McNicholas 2016). Take, for example, the German "Sicherheit" (which could mean, next to safety and security, also certainty) or the Hebrew "bitachon" (which means security but also trust and faith) or the Dutch "veiligheid" (which means safety as well as security). Meaning differences between "security" and "safety" do not always exist linguistically; there can be more meanings of the words. Non-native English-speaking maritime professionals are thus forced to take over the English terminology, which may cause communication issues, thus leading to different understandings and practices of maritime safety and security.

There are many more aspects leading to conceptual and practical ambiguity, even rivalry, between maritime security and safety. Given the long existence of SOLAS as international maritime safety legislation and the, in comparison with SOLAS, short existence of the ISPS Code, the current generations of maritime professionals are automatically more maritime *security* focused, whereas previous generations have been more maritime *safety* focused.

Maritime security logic has dominated the maritime industry since 9/11 and two attacks on US naval destroyers in 2000, the *USS The Sullivans* and the *USS Cole*, of which the latter was claimed by al-Qaeda (Metaparti 2010). Maritime security through the ISPS Code and its new security roles and rigid bureaucracy (Liss 2011) has been in particular focused on counterterrorism, shifting the focus in the maritime industry from safety to security and making it seem as if security practices surpass safety practices.

Practically though, maritime safety still matters in everyday maritime professional life. Shipping crews, port workers, and the overall maritime professional population seem to have more safety awareness than security awareness as safety awareness is more naturally adapted to and thus more integrated into daily routine to effectively *support* daily routine. Maritime safety (awareness) appears more important as well because maritime security (awareness) is not as much a part of the daily routine as safety is: maritime terrorist attacks, the main focus of the ISPS Code, barely happen (Metaparti 2010). However, occupational hazards occur far more frequently, leading to safety awareness being significantly more integrated into daily routine, reflected in having to wear personal protection equipment (PPE), holding onto bars, and being careful with dangerous goods – security threats such as piracy, drug crime, or terrorism are far more invisible and rather alien to maritime workers, also security workers, in ports and on deck, resulting in professionals not taking maritime security (awareness) as seriously as maritime safety (awareness) (Eski 2016).

Moreover, "What is maritime security?" as Bueger (2015) wonders. It is not as established as maritime safety but still "replaces or subsumes older, established concepts, as well as relates to more recently developed ones," namely, "sea power, marine safety, blue economy, and human resilience" (ibid. 160). It indicates that safety is a part of maritime security, which is not necessarily experienced by the professionals in the maritime industry, leaving "maritime security" behind as a buzzword with no definite meaning, and it merely "achieves its meaning by actors relating the concept to others, by attempts to fill it with different issues and by acting in the name of it" while "vary[ing] across actors, time, and space" (ibid. 163).

On top of it, the ambiguity of the two apparently different concepts can also blur both their practices, which further complicates operational realities on deck and at the docks. Right after the financial crisis and austerity policies hit port communities throughout the world, in particular from 2010 onward, port workers feared losing their job, not being able to sleep, while having to handle containers in cranes and vessel carriers for which they must be focused and awake and must comply with strict regimes regarding their working hours (Eski 2016). Due to the same fear of losing one's job, these employees as "safety risks" can also become "security threats" because they might steal something or turn corrupt and assist criminal organizations that run illegal drug trafficking operations in ports (Eski and Buijt 2016). Both challenges must be dealt with security personnel, usually through different norms and rules; however, in reality, time and context can blur being a "safety risk" and/or "security threat" which may undermine maritime logistics (Cowen 2007).

The "safety risks" and "security threats" blur as well due to the ISPS Code's focus on (counter) terrorism. Sometimes, it demands that entries must be closed and secured, but due to safety regulation revolving around fire hazard, these points of access ought to remain open. At a petrochemical port facility, when an oil tanker is anchored, (extra) escape gangways are required to escape from a fire on board, but this conflicts with ISPS Code regulation regarding gangways, as (extra) entries means having more possibilities for outsiders and threats to enter a ship. Or think of the doors of a port facility being locked to minimize the security risk of cargo theft, but must be opened as soon as a chemical gas of a dangerous good spreads itself. What prevails? Security or safety? Or consider SSOs and PFSOs who take care of both safety-related issues, such as applying first aid, and of security issues, like stopping unauthorized individuals from entering a ship and/or a port facility. When letting authorities, such as the police or customs agencies, enter port facilities and ships to do security inspections, due to the principle of "safety first" and the different safety measures on board and on facility perimeters, these authorities are forced by an SSO or PFSO to wear personal protection equipment (PPE). It happens occasionally that the police and border control authorities that are tasked to keep a port secure are aggravated by and get into a conflict with PFSOs and SSOs who demand compliance with safety rules.

Conclusion

In conclusion, although the ISPS Code symbolically prioritizes the unclear concept and practices of maritime security over maritime safety, it is important to account for maritime safety practices as still being (much more) common in the everyday of the maritime industry. At the very least, there seems to be conceptual and practical ambiguity *between* and *because* of the two, which leads to rivalry at operational level that could result in serious damages (Knapp and Franses 2010). It could be interesting to have the two concepts integrated, without ignoring their (different) real effects, into what is being increasingly developed a framework of maritime resilience (Sauser et al. 2018).

Mercenary and Private Military

Spyridon Triantafyllou

Keywords
Private security · Contractors · Security services · Mercenaries · International law

Definition

Non-state security providers, companies offering private military and security services.

Introduction

Other similar or related terms: *Private Military Companies* (PMCs), *Private Security Companies* (PSCs), *Private Military Firms* (PMFs), or *Private Military and Security Companies* (PMSCs). For practical reasons, the adoption of generic term "PMSCs" is suggested, despite the controversy upon the distinction of these terms (Singer 2003).

According to the UN Draft Convention on Private Military and Security Contractors (2011), PMSCs offer security or military services, defining "security services as armed guarding of things or people, knowledge transfer with security/police applications, development and implementation of informational security measures and other related activities."

Private Security Companies (PSCs) – compared with Private Military Companies (PMCs) – are not involved directly with combat activities and operate under a greater mandate, offering not only military services, but also other security services on a strategic, tactical, and operational level, such as policing, advising, and logistical support. Alternatively, the distinction between military and security services derives from the nature of the services, in that

participating as a combatant or offering other services, respectively.

Private Military Firms (PMFs) term indicates the contemporary trend of privateering and outsourcing of security functions, which are inherently governmental functions as security is a public good.

The type and extent of private security services varies depending on the host nation and the contractor (company). There may be active and/or passive security measures in place, while focusing on police operations, several security services are offered including protection of assets or any other activity for which carrying or operating a weapon in performance is required. Finally, peacekeeping and other support mission services are offered related to security sector reform (reform of the police and the judiciary), including training and capacity-building activities.

Need for Private Security Services

According to the Montreux Document (2008), Private Military and Security Companies (PMSCs) are "private business entities that provide military and/or security services, irrespective of how they describe themselves. Military and security services include, in particular armed guarding and protection of persons and objects, such as convoys, buildings and other places; maintenance and operation of weapons systems; prisoner detention; and advice to or training of local forces and security personnel." In addition, according to the International Code of Conduct (ICoC) (2010), private security services may be offered by unarmed personnel.

The scope of PMSCs activities is to protect assets (persons, properties, proprietary information, reputation) in countries where security is deficient or when conflicts or disasters necessitate increased security measures.

A recent motion for action of the European Parliament highlights the importance of PMSCs in support of operations abroad. Such private entities: "1. *(should)* play an important complementary role in aiding the state's military and civilian agencies by closing capability gaps created by increasing demand for the use of forces abroad, *(. . .)* 3. compared to national troops, can provide valuable local knowledge and, frequently, cost savings, although it must be ensured that quality is not undermined, *(. . .)* 4. no activities should be outsourced that would imply the use of force and/or active participation in hostilities, except for self-defence *(and)* any participation by private security companies in military operations must be justified, with clearly-defined objectives that can be verified using tangible indicators, have a fully-detailed budget and a specific start and end date, and be governed by a strict code of ethics *(. . .)*" (European Parliament 2017).

Clients of security services might be governments, international organizations (i.e., the United Nations, European Union), non-corporate security providers (i.e., host government military and police, local militias, peacekeeping forces), humanitarian organizations or NGOs, private industries to ensure their economic interests (i.e., oil, gas, mining, transportation sectors), or journalists. In such cases, usually there is no guarantee for protection due to weakened governance in terms of stability and development of the host nation.

Prior to signing a contract with PMSCs, potential clients should take into consideration if the company complies with the law and a code of ethics, particularly in: "a) acquiring information relating to the principal services the PMSC has provided in the past; b) obtaining references from clients for whom the PMSC has previously provided similar services to those the contracting state is seeking to acquire; c) acquiring information relating to the PMSC's ownership structure and conducting background checks on the PMSC and its superior personnel, taking into account relations with subcontractors, subsidiary corporations and ventures" (Montreux Document 2008).

Several initiatives have taken place to establish accountability and transparency mechanisms of PMSCs and their activities with respect to international human rights and humanitarian law, national law, or other terms of the contract. These initiatives highlight the procedures for the selection of and contracting with PMSCs, as well as the assessment of risks so as to determine what

security services are necessary and why, based on a cost-benefit analysis both for host nation and contractor.

In terms of accountability, three phases are to be taken into consideration when focusing on contractors and their distinct relationships with the hiring, host, and home states: (1) the *contracting phase* (scope of activities outsourced, screening history and vetting); (2) the *in-the-field phase* (monitoring mechanisms and other regulatory bodies); and (3) the *post-conduct phase* (civil liability and criminal culpability issues of private contractors and their personnel) (Huskey 2012).

Jobs Performed by Mercenaries

Private security firms hire private military specialists who play key role in armed conflicts assuming their expertise, their integrity, and their apolitical origin (Mandel 2001). This is not a new phenomenon, as mercenaries were hired and extensively utilized to establish security and promote private interests from the Medieval times to nineteenth century. Some examples are the *condottieri* in Italy during the Renaissance period, the Swiss mercenaries who fought for the French until 1793, *privateering* as a wartime practice against pirates, and the *mercantile companies* or forces for the British, Dutch, and other colonies (see Andreopoulos and Brandle 2012).

Indicative of the types of private security services are the findings of a survey conducted to depict the role of the private security industry in support of humanitarian organizations, operating in complex and hostile environments (i.e., countries or regions in Central Africa, Middle East, North Caucasus). According to a Humanitarian Policy Group report (2008), the importance of security services in humanitarian operations, by both international and local security providers, is presented as follows (arranged in descending order):

- Unarmed guards for facilities/residences/project sites
- Physical security for premises
- Security management consulting
- Security training for staff
- Risk assessment/threat analysis
- Information services
- Armed guards for facilities/residences/project sites
- Standby security
- Mobile escorts (armed)
- Unarmed bodyguards
- Critical incident/crisis management
- Hotlines
- Logistics
- Armed bodyguards
- Mobile escorts (unarmed)
- Unarmed third party security
- Armed third party security

Mercenaryism should be differentiated from Private Military and Security Companies (PMSCs), which are private legal entities employing a significant number of staff on a fixed-term basis and oftentimes higher salary.

According to Article 47 of Protocol I additional to the 1949 Geneva Conventions, applicable in international armed conflicts, a mercenary is "any person who: a) is specially recruited locally or abroad in order to fight in an armed conflict; b) does, in fact, take a direct part in the hostilities; c) is motivated to take part in the hostilities essentially by the desire for private gain and, in fact, is promised, by or on behalf of a Party to the conflict, material compensation substantially in excess of that promised or paid to combatants of similar ranks and functions in the armed forces of that Party; d) is neither a national of a Party to the conflict nor a resident of territory controlled by a Party to the conflict; e) is not a member of the armed forces of a Party to the conflict; and f) has not been sent by a State which is not a Party to the conflict on official duty as a member of its armed forces."

Although the motivation of the contracted is not always clear, PMSC employees act as mercenaries, if all these criteria meet cumulatively. In such cases, they are not considered as combatants, and, thus, they are not entitled to prisoner of war (PoW) status, according to the law of armed conflict.

Locations Used of Private Military and Security Companies

Private Security Companies as a whole appeared in the 1970s, but they were especially preferred and deployed during the "war on terror," particularly in Afghanistan and Iraq wars after 9/11 attacks and against the Islamist State of Iraq and the Levant (ISIL/ISIS) terror group, as well in other post-conflict areas or situations.

Either offering purely security services or other auxiliary services, there are several PMSCs, which operate in several areas worldwide. Usually, they support governments (host, hiring) or organizations to establish to national security, public order, or peace-building capacities in areas suffering from sociopolitical stability, civil wars, humanitarian crises, or lack of governance ("failed states").

Such examples include, but are not limited to, the United Nations perspective, which hired PMSCs to operate in high-risk environments especially during the first decade after the 2000s: provision of civilian personnel in UN missions in *Haiti and Liberia* (2004); peacekeeping and contingency operations in *African countries* (2003, 2009); armed or unarmed security personnel for the protection of UN officials in *Iraq* war; physical security and training in *Kenya* and *Afghanistan*; supply helicopter transport and satellite network in *East Timor* (2008); logistical and intelligence support in *Sierra Leone* (2000, 2003) or *Democratic Republic of Congo* (2001); logistics connected with security (i.e., information-gathering and intelligence-like services), such as provision of public security in *Iraqi* referendum (2005); monitor sanctions in *Angola* (2001); intelligence operations in *Iraq*, *Sudan*, and *Afghanistan*; removal of unexploded landmines in *Sudan* (2006) and of improvised explosion devices in *Nepal* (2007); clearance and training in *Bosnia* and *Mozambique* (2008); or demining of the buffer zone of *Cyprus* (see Østensen 2011).

Over the last decade and because of attempts to legally regulate private security sector operating abroad as discussed next, PMSCs have transformed their activities according to security sector reform initiatives or other procurement-oriented services into human rights training, capacity building of local military and police corps, and military to civil transition support.

Additional Issues and Concerns

On September 16, 2007, in Nisour Square (Baghdad, Iraq), a US embassy convoy escorted by security guards of "Blackwater Security Consulting" was attacked, who in turn fired back, resulting in 17 dead and 20 injured civilians. The shooting incident was the critical juncture; since then, mercenaries are in the public eye and more regulation of the field under the international humanitarian law was initiated to deal with unnecessary or disproportionate violence PMSC personnel.

Aiming to clarify the international legal framework regarding PMSCs and to benchmark good conduct of private security industry, initiatives run by Swiss Government and other actors led to the Montreux Document (2008) and finally to the International Code of Conduct (ICoC) (2010). According to the ICoC, the main *principles* refer to general conduct, use of force, detention, prohibition of torture, trafficking in human beings and sexual exploitation, discrimination, and identification and registering policies for PMSCs and their personnel, while the primary *commitments* refer to incorporation of code of conduct into company policies, selection and vetting of personnel and subcontractors, training, incident reporting, and liability issues regarding PMSCs.

Moreover, in 2010, a "Draft of a possible Convention on Private Military and Security Companies (PMSCs) for consideration and action by the Human Rights Council" was annexed in a Report of "UN Working Group on Use of Mercenaries as a Means of Violating and Impeding the Exercise of Rights of Peoples to Self-Determination." The UN has attempted to introduce restrictive and universal standards (including states and international organizations), applicable not only in armed conflicts, but in all certain situations involving private security contractors with respect to international humanitarian law.

All these legal, not-binding though, documents attempt to set out principles and standards for

PMSCs based on international law and accountability, but they commit only the signatory parties as there is a "soft law" approach for industry regulation.

Private security services constitute a significant challenge for an international system. On the one hand, security is public responsibility connected with national sovereignty. On the other hand, the non-statutory nature of contractors is attached with financial motivation and business practices and, therefore, impacts on the national response to regulation of private security. The main question under scrutiny is whether private entities can exert violence by supporting nations or other companies and in what manner. Therefore, apart from the legal framework, a code of conduct is essential to oversight private security contractors.

Conclusion

To conclude, it is widely accepted that the use of force by PMSCs should be restricted in to use in self-defense or defense of others (like civilians), which implies the nature of PMSCs. Consequently, private security contractors do not have more privileges or rights to use force than other civilians. Finally, nowadays, PMSCs support the mission of military or police, but they have a distinct role since the state agents have the monopoly of violence to ensure public safety, including powers of arrest, search, and seizure (Buzatu 2015).

Natural Hazards

Sara Bonati
SAGAS, Università degli studi di Firenze, Florence, Italy

Keywords
Hazards · Natural · Risk · Disaster

Definition

Natural hazards are geophysical processes that deviate from the norm by resulting in dangerous situations. They include sudden processes and slow long-term processes, such as expected and unexpected ones.

Introduction

Natural hazards are usually defined as the possibility that something dangerous may happen or that a risk can be manifested (Montz et al. 2017). According to Ball (1979), natural hazards are the manifestations of geophysical systems that deviate in a meaningful way from their long-term average. Similarly, Smith (1992) has defined natural hazards as extreme fluctuations or deviations of environmental processes. Other definitions consider the human dimension, such as dangerous scenarios that develop from the interaction between nature and human society (Burton et al. 1978).

The opposition between nature and society is not always enough to explain all the possible types of hazards, especially when the interaction is not clear or it does not fall into specific time-place limit (Khan 2012). This fusion between "natural" and "social" dimensions is increasing also in the approaches adopted to study hazards. Thus, it is frequent for studies of geophysical sciences to address social components of natural hazards (e.g., Jayasingha 2016), such as multi-disciplinary approaches to the topic (e.g., Frigerio et al. 2016). Today, natural hazards are broadly recognized as hazards that have natural, social, and socio-natural origins. Paron (2013) defines "hazards" as "highly anthropocentric in nature," being the result of an interaction between a biophysical process and an "occupying" group of people/community. Stewart (2013) elaborated that according to the science of natural disasters, hazards are causative events that nature shapes and produces, while the external negative consequences have to be investigated in the society.

In social sciences today, it is broadly accepted the idea that the concept of natural hazard is socially constructed, and therefore it is possible to talk effectively about them only if they are interpreted in relation to society. As Kelman (2018) stated, all hazards are "socially mediated." Kelman argued that when a natural process is mediated by society and its characteristics are modified in a way that makes it hazardous, it

© Springer Nature Switzerland AG 2021
L. R. Shapiro, M.-H. Maras (eds.), *Encyclopedia of Security and Emergency Management*,
https://doi.org/10.1007/978-3-319-70488-3

is not possible to continue to talk about "natural" hazard. Thus, the distinction between natural hazard and human hazard is in some way sterile because it is quite complicated to distinguish among the various origins of the phenomenon and to identify the limits of social actions in transforming the environment. This assumption is also supported by Wisner et al. (2012) in that the natural environment is not considered entirely natural because it is subjected to human action: "Hazards are not entirely free of human influence, although some hazards are difficult to influence at a large scale such as space weather and earthquakes" (p. 24). The definition given by UNISDR (2017) recognized the potential role of humans in increasing the "hazardousness" of natural processes (also see Kelman 2018).

The human element in hazard interpretation prompts another question about the "unexpected" dimension of hazards. Usually, hazards are considered as something happening suddenly in an unexpected way; however, the role of humans in such hazards suggests that these hazards could be expected. Expectation does not mean that we are able to know the exact moment such hazards will occur, just that they will happen in time. For instance, some floods have origins in human intervention along rivers, fires can be a consequence of changing the bio-composition of forests, and even earthquakes can be produced by the human activity of hydraulic fracking.

Classification of Natural Hazards

There are multiple ways to classify natural hazards. One method is according to their "physical dimension" at the origin of the event. For example, according to Bokwa (2013), there are geological hazards, like earthquakes and landslides; meteorological hazards, like cyclones and hurricanes; hydrological hazards, like floods; oceanographic hazards, like sea level rise; hazards connected with vegetation; and extraterrestrial hazards. UNISDR (2017) classified biological hazards, environmental hazards (that can also be technological), geological or geophysical hazards, hydrometeorological hazards, and multi-hazards. Another classification is according to their time-space manifestation and magnitude. Hazards are natural transformations of the environment that happen at both the local and global levels and that can be sudden or slow in their manifestation. The low probability that these events become disasters is usually responsible for low attention to the potential risk they represent (Montz et al. 2017).

Distinguishing Between Danger and Hazard

Danger is the possibility that something happens to an individual and that produces damages. More specifically, danger is the possibility that an individual will be harmed and is focused on the physical damages that the person or persons can suffer in terms of health and life. In contrast, a hazard is a process that can produce dangerous situations from which an individual can be harmed or be in danger. The definition of hazard is more focused on the "probability" that something happens. For example, a place is defined as hazardous if there is a high probability that a particular dangerous phenomenon will take place.

Distinguishing Between Risk and Hazard

Similarly, risk and hazard are two concepts that are usually confused; thus, it is difficult to identify a common interpretation that defines them without further discussion. This problem is increased by the fact that not all the languages can have direct translations of the concepts (this is the case, e.g., of Italian, where there is not a correspondence for "hazard" word; and this can become more complicated with languages that adopt a different alphabetical system).

In disaster studies, risk is usually considered the first path to disaster; it is the condition without which a disaster cannot take shape. Risk requires two conditions: an element that produces the risk and the possibility of damages (i.e., danger,

exposure, vulnerability). In contrast, hazards represent those phenomena that can "expose" a person to vulnerable situations (Kelman 2016). Another difference in these two terms is in a research approach; the risk approach focuses mainly on the damages, while the hazard approach focuses on the processes that can produce those damages.

Distinguishing Between Natural Hazards and Unnatural Disasters

According to a World Bank report (UN 2010), "the adjective 'UnNatural' in the title of this report conveys its key message: earthquakes, droughts, floods, and storms are natural hazards, but the unnatural disasters are deaths and damages that result from human acts of omission and commission" (p. 1). Not all earthquakes become disasters. If a society has the capacity to deal with a particular event and this takes place without the production of damages, that is a hazard but not a disaster. As Quarantelli wrote: "A disaster is not a physical happening. It is a social occasion" (2005, p. 343; see also Squires and Hartman 2013). Disasters and hazards are distinguished by the social dimension that Birkmann (2006) and Blaikie et al. (2004) define as vulnerability (see also Wisner et al. 2012).

In disaster studies, hazard and disaster are distinguished by the point of view adopted. Accordingly, Gaillard and Mercer (2013) identify two paradigms in disaster studies: hazard paradigm and vulnerability paradigm. The hazard paradigm is focused on the dynamics of the physical happening. *Hazard* is a "judgment" of a normal (and sometimes essential) natural process that comes from choices adopted from societies over the long term, choices that are responsible for the dangerous dimension of events (Kelman 2009). This paradigm is founded on works by Burton et al. (1978) and Kates (1971) who say that disasters come from the inability of people to "adjust" to avoid damages. Natural hazards can be also read as resilient processes put in place by nature to adapt to and answer to human transformations. The focus is on the ability to deal with and understand the level of risk to which people are exposed. On the other side, the vulnerability paradigm is oriented to discuss the social dimension of the event in terms of damages and exposure. It focuses on the level of vulnerability of the people exposed and on the processes that were brought to this. In particular, processes of marginalization and lack of rights are considered, according to political ecology and environmental justice (e.g., Bolin and Kurtz 2018; Cutter 2012; Wisner et al. 2004).

Conclusion

Natural hazards are slow and fast processes that can produce damages and that can become disasters if some risks take shape. The hazard research approach is focused mainly on the "nature" of the process and its dynamics and on the following human adjustments. Not all hazards become disasters; it depends by the presence of vulnerability conditions. In literature the expression "natural hazard" is accepted and used, and it refers to different physical processes, although some authors discuss the "natural dimension" of some hazards. To conclude, hazards, risks, and disasters have not to be confused, and the dimension of vulnerability is at the basis of their distinction.

Natural Hazards: Earthquakes

Hua-Lun Huang
Department of Sociology, Anthropology, and Child and Family Studies, University of Louisiana, Lafayette, LA, USA

Keywords

Major Earthqake · Secondary Earthquake · Geographic Location · Extraordinary Event · Ordinary Event

Definition

An earthquake is the shaking of the surface of the Earth. It is a force that can cause great damages to

man-made structures, such as airports, amusement facilities, bridges, commercial buildings, dams, government buildings, harbors, historical constructions, hospitals, libraries, military bases, museums, nuclear power plants, public statues, religious buildings, residential houses, roads, and schools. It can trigger massive landslides, mudslides, and tsunami as well.

Introduction

Earthquakes are a scary thing for numerous people, especially for those who live in areas rarely or never stricken by seismic activity. The reason for this collective fear is obvious:

The occurrence of earthquakes, at least in the early 2020s, remains unpredictable. As a result of this unpredictability (or capriciousness), no one can be certain that his/her property will never be damaged or destroyed by earthquakes (especially major ones) in the future.

While earthquakes can bring great damages to buildings and infrastructures, most of them tend to be moderate or insignificant. With this in mind, classifying earthquakes is a crucial job for those researchers who want to compare the social impacts brought about by earthquakes.

In terms of classifying earthquakes, seismologists and other investigators undoubtedly have many factors they can focus on, such as power (P), time (T), scope (S), or duration (D). Besides PTSD, seismologists can also concentrate on pattern when categorizing earthquakes.

For the purpose of comparison, seismic activities are classified into *MIE*, *MIO*, *MNE*, *MNO*, *SIE*, *SIO*, *SNE*, and *SNO* types in this entry. To explain this classification, this entry will aim to address the following two "big questions":

First, how to classify earthquakes from the angle of sociology?

Second, what are the defining characteristics of major and secondary earthquakes?

Technical issues related to earthquakes, however, will not be discussed for they are beyond the scope of this entry. These issues include, but are not limited to, the subsequent questions:

First, what are the most important technologies (i.e., earthquake warning technologies) that can help seismologists predict the happening of earthquakes?

Second, what are the devices that can help residents (especially those who live in regions frequently stricken by earthquakes) reduce the impacts of earthquakes?

Third, what are the best architectural designs that can prevent buildings (especially tall ones) from collapsing when major earthquakes take place?

Finally, what are the techniques that can help architects deal with the problems caused by earthquakes (e.g., liquefaction, sinkhole, landslide, etc.)?

A Sociological Classification of Earthquakes

In criminology and sociology, earthquakes are usually defined as a geological or geographical phenomenon. Because of this designation, the great majority of criminologists and sociologists did not attempt to classify earthquakes – after all, seismologists have already proposed several classification systems in the twentieth century (e.g., the Richter magnitude scale). As a result, advancing another categorization for earthquakes seems unnecessary.

Proposing another classification system for earthquakes, however, is by no means redundant – from the perspective of security (or emergency management), the taxonomies proposed by Charles Richter and other seismologists did not clearly and directly mention the social problems caused by earthquakes. Accordingly, the Richter magnitude scale and other similar measurements tend to be inadequate/insufficient in helping social scientists examine the relation between earthquakes and social actions (particularly criminal and deviant behaviors).

Based on the statements above, this entry will construct a classification system for earthquakes (which tend to concentrate in certain regions on earth, such as those countries located near or on the Ring of Fire). Three variables will be used to

create this system. They are intensity, geographic location, and social impact.

The Construction of a Classification System for Earthquakes

In sociology, one of the most significant approaches in explaining the emergence of a macro phenomenon (e.g., the formation of an extremist social movement) is structuralism. According to this approach, the appearance of a macro phenomenon always involves the interaction of two sets of variables. The first set is composed of structural factors, such as ecological resource, government pattern, religious institution, population density, and technological level. According to Giddens' (1986: 25–34) theory of structuration, these factors can help a society maintain stability or demonstrate stable features. They can be characterized as "temporal continuity" (Little 1991:103) because they will last for years and serve as boundaries constraining the actions of social members.

The second set of variables is composed of actors/agents who can establish various relationships (Roth and Wittich 1978: 38–46). Unlike structural factors that can help a society preserve miscellaneous laws/rules and maintain "administrative and regulative" order (Roth and Wittich 1978: 51), the actions taken by agents may trigger changes in a society. Agents are therefore the sources of progression/transformation and the producers of temporal variation.

Inspired by the three concepts of structure, agency, and interaction (i.e., the interplay between structure and agency), earthquakes are grouped by three-level variables in this entry. The first variable, *intensity*, stems from the concept of structure. It refers to the magnitude or geographical reach of an earthquake. The second variable, *geographic location*, comes from the notion of agency. It represents the variations of earthquakes in space or physical position. The third variable, *impact*, derives from the idea of interaction. It denotes the damages (which can be visible/serious or invisible/minor) that an earthquake causes in a certain area. Each of the three variables is divided into two levels:

First, *intensity* is split into major (M) [which are those seismic activities that reach 7.0 or higher in the Richter magnitude scale] or secondary (S) [which are those seismic activities that do not exceed 6.9 in the Richter magnitude scale].

Second, *geographic location* is divided into involved (I) [which are those earthquakes that can directly send seismic waves to populated areas because the epicenter is close to or on the verge of human settlements] or uninvolved (U) [which are those earthquakes that do not directly send seismic waves to any populated areas because the epicenter is far away from human settlements].

Finally, *impact* is divided into extraordinary (E) [which are those seismic activities classified by historians or seismologists as textbook examples or landmark events] or ordinary (O) [which are those seismic activities not regarded by historians or seismologists as model or milestone instances].

Based on the different combinations of the above-listed ranked variables, a classification system for earthquakes can be seen in the following:

- The *MIE* type (i.e., *major* earthquake + *involved* + *extraordinary event*).
- The *MIO* type (i.e., *major* earthquake + *involved* + *ordinary* event).
- The *MUE* type (i.e., *major* earthquake + *uninvolved* + *extraordinary event*).
- The *MUO* type (i.e., *major* earthquake + *uninvolved* + *ordinary* event).
- The *SIE* type (i.e., *secondary* earthquake + *involved* + *extraordinary event*).
- The *SIO* type (i.e., *secondary* earthquake + *involved* + *ordinary* event).
- The *SUE* type (i.e., *secondary* earthquake + *uninvolved* + *extraordinary event*).
- The *SUO* type (i.e., *secondary* earthquake + *uninvolved* + *ordinary* event).

The classification scheme advanced in this entry therefore includes eight categories of earthquakes. Since each typology has certain implications in security and emergency management, they will be summarized in the section of Conclusion. Before inspecting the possible

consequences brought about by seismic activities, the defining characteristics of major and secondary earthquakes will be first addressed. These core features will be exemplified by earthquakes that took place in Central Asia, East Asia, North America, and the South Pacific in the twentieth and twenty-first centuries.

The Defining Characteristics of Major and Secondary Earthquakes

As stated, earthquakes (no matter whether they are contemporary or ancient cases) can be characterized as *MIE*, *MIO*, *MNE*, *MNO*, *SIE*, *SIO*, *SNE*, or *SNO* type. That means some earthquakes are fairly similar, some are partially similar, some are considerably dissimilar, while others are totally different.

Given that seismic activities are diverse in power, epicenter, or aftermath, comparing the central qualities of major and secondary earthquakes is therefore an essential component in helping crime researchers identify those circumstances under which seismic activities can become criminogenic (i.e., identify those opportunity structures that can provide people with chances to commit crime or launch extremist movements).

In the following, the central features of major earthquakes will be first inspected and contrasted. Then the main traits of secondary earthquakes will be examined and compared.

MIE-Type Earthquake

According to reports/measurements, some earthquakes that took place on earth in the past decade reached 7.0 or higher in the Richter magnitude scale – some were somewhere between 7.0 and 8.9, while a small number of them were above 9.0. No matter whether an earthquake attained the highest level in the Richter magnitude scale (i.e., the range of 9.0 to 10.0), seismic activities (if they are close to a city) can always severely damage buildings and infrastructures if they reach at least 7.0 or higher in the Richter magnitude scale. For this very reason, all seismic activities that arrive at 7.0 or higher in the Richter magnitude scale can be classified as major earthquakes.

Major earthquakes, on the other hand, do not concentrate in particular areas only – according to records, some took place in regions far from cities (e.g., deep ocean, desert, isolated island, etc), some happened in districts not too close or too far from cities, while others occurred on the verge of densely populated cities. In this regard, the *MIE*-type earthquakes can always bring great damages to a city because the location of these shakings is very close to a populous area, which allows the *MIE*-type quakes to deeply get involved in the routine life of human societies.

So the *MIE*-type earthquakes are by no means trivial or negligible events. On the contrary, they are extraordinary incidents for they can cause extensive damages in stricken cities. This devastating effect can be plainly seen in the Japan earthquake of 2011, the Haiti earthquake of 2010, the Sichuan (China) earthquake of 2008, the Taiwan earthquake of 1999, the Tangshan (China) earthquake of 1976, the Alaska earthquake of 1964, the Chile earthquake of 1960, and the San Francisco earthquake of 1906 (see Freedman 2013; Miles 2017; Palmer 2012; Svistova and Pyles 2018; Takezawa 2016; Yong and Booth 2011).

Although the *MIE*-type earthquakes can lead to great casualties when they take place, accurately predicting the occurrence of this kind of earthquakes (at least so far) is not likely. For this reason, the *MIE*-type earthquakes can always turn a stricken region into a hotspot of crimes if people of that area fail to fix damaged or derelict buildings as soon as possible (for these structures can become shelter for delinquent and marginalized populations).

MIO-Type Earthquake

Like the *MIE*-type earthquakes, the *MIO*-type quakes are powerful and potentially destructive. However, the *MIO*-type earthquakes do not occur in regions where seismic waves can directly and effectively affect metropolitan areas (or megacities). Instead, these quakes take place in sparsely populated places, such as countryside, peripheral rural towns, and gemeinschaft communities. That makes the *MIO*-type earthquakes look like a matter of little consequence.

While the *MIO*-type quakes rarely draw attention of the public because they do not happen in densely populated districts and will not bring massive damages, this does not imply that these earthquakes are totally noninfluential or negligible. Instead, the *MIO*-type quakes, just like the *MIE*-type quakes, are noteworthy because they allow the public to witness the destructive power of a major earthquake – in other words, the *MIO*-type quakes still can help seismologists or the public collect data about major shakings, even though these quakes usually strike tiny communities or small rural towns.

No matter how many *MIO*-type quakes will take place in the future, the media normally will not report these seismic movements in detail for they are not dramatic or spectacular enough in capturing the attention of the public. With this in mind, classifying these earthquakes as common events seems adequate.

Of the numerous earthquakes that have happened in the past two decades, the Altai earthquake of 2003 appears to be the best example of the *MIO*-type quakes. First, the intensity of this earthquake was higher than 7.0 in the Richter magnitude. Second, it did strike some rural communities. Nevertheless, the Altai earthquake was not considered to be spectacular because the casualties it caused were much lighter than those brought about by the *MIE*-type quakes.

In brief, the Altai quake did not have an extremely high death toll. For this very reason, finding academic books or reports on this quake is therefore extremely difficult, if not impossible. Wikipedia (see the article entitled *2003 Altai earthquake*) probably is the only source that can help the public obtain critical information on this earthquake.

MUE-Type Earthquake

Compared to the *MIE*- and the *MIO*-type earthquakes, the *MUE*-type quakes are far less common. The reason for this is that finding earthquakes (especially modern ones) that simultaneously exhibited the following three qualities is extremely difficult, if not impossible:

First, they are powerful (i.e., they reached 7.0 or higher in the Richter magnitude scale). Second, they do not send seismic waves to human settlements. Third, they are landmark events for humans, even though they do not have direct impacts on human communities.

Based on the three criteria listed above, it seems adequate to argue that the *MUE*-type quakes concentrated in prehistoric times:

Before humans started to establish settlements in the middle (and/or final) period of the Stone Age, certain strong quakes did take place on earth. Since some of these earthquakes were so powerful that mountain building and/or continental drift processes were triggered (see Frisch et al. 2011; Fountain 2017), such quakes did constitute milestone events for humans (although they happened in periods when structured settlements created by humans had not had taken shape), put differently, the mega-earthquakes that occurred in the Stone Age or earlier shaped the layout of continents and islands on earth. As a result of this geographic arrangement, numerous activities that humans engaged in were constrained by geographic characteristics. For example, modern-day Chinese peasants are far more likely to engage in small-scale farming than their American counterparts because China lacks areas that resemble the Great Plains of North America.

In brief, the *MUE*-type quakes are critical events for humans as they created the geographical spaces of the modern world, such as continents, gorges, islands, mountains, plateaus, peninsulas, and valleys. Such spaces, in turn, serve as physical boundaries of human activities. This may explain why humans always face particular environmental limitations after they have permanently dwelled in a certain region. For example, most parts of America do not produce rare earth-like scandium, yttrium, and neodymium. Because of this constraint, America must import rare earth from overseas, especially China, on a routine basis.

MUO-Type Earthquake

Unlike earthquakes of the *MIE* and *MUE* categories, the *MUO*-type quakes tend to play a trivial, if not totally inconsequential, role in human history. This "minor status" seems to be related to the following reasons:

First, the *MUO*-type quakes usually take place at the bottom of the ocean. Accordingly, these earthquakes normally will not affect human settlements, particularly large urban areas. Given that the *MUO*-type quakes, on average, do not seem to affect any human communities, the public naturally will not pay close attention to these seismic activities. This strongly implies that the *MUO*-type quakes are very likely to be forgotten by the public if they are not recorded by seismologists or other researchers.

One representative example of the *MUO*-type quakes is the underwater shaking that took place in the sea area near Taiwan's Hengchun peninsula in December, 2006 – even though this quake reached 7.1 in the Richter magnitude scale, it did not cause any damages in Taiwan and the Philippines. Seismologists therefore view this event as just a regular energy release from the inside of the earth (see the article entitled *2006 Hengchun earthquakes* in Wikipedia).

SIE-Type Earthquake

While several major earthquakes have struck both densely and sparsely populated areas on earth in the past 20 years, such quakes appear rare in human history. In other words, the great majority of earthquakes that happened in the modern world tend to be secondary because these seismic activities can be found in many places on earth almost every week.

Although most quakes that took place in the twentieth and twenty-first centuries look minor or insignificant, this does not imply that all of them are inconsequential. As a matter of fact, some secondary quakes are noteworthy because they can bring "hidden damages" to buildings, bridges, and roads, especially those made out of shoddy materials:

Like major earthquakes, secondary quakes can undermine the infrastructures of a city/metropolitan area as well. Such harms, however, seem much lighter than those caused by major earthquakes because secondary quakes usually are not powerful enough in bringing serious or immediately identifiable damages to a building or facility – this may explain why the destruction brought about by secondary quakes can remain undetected or unnoticed for a period of time. Under such circumstance, a seemingly normal building or facility may suddenly collapse or disintegrate if this structure experienced the above-noted "hidden damages" several times.

One probable case of the *SIE*-type quakes is the Hualien earthquake:

In February 2018, Hualien, the largest city of eastern Taiwan, was stricken by an earthquake. This quake, if it had had not caused high casualties and widespread injuries, is not shocking at all for its intensity merely reached 6.4 in the Richter magnitude scale. The Hualien earthquake, however, was not an ordinary shaking – not only did it partially or critically damage many buildings in Hualien, it also killed or wounded more than 300 people. All of these losses and casualties motivated Japan and Singapore to send rescue team or relief supplies to Taiwan (see the article entitled *2018 Hualien earthquake* in Wikipedia).

No matter whether Hualien will experience another earthquake in the near future, the high casualties caused by the 2018 earthquake in Hualien seemed to be closely related to the accumulative effect of "hidden damages." That is, Hualien, like those cities located on the Ring of Fire, has experienced numerous secondary earthquakes in the twenty-first century. Since these shakings might have led to structural deteriorations, which might remain invisible or look inconsequential for a long period of time, in the past 20 years, such structural declines or deformations (which probably had reached the critical point of disorganization or breakdown in 2018) helped the 2018 earthquake become a devastating one.

SIO-Type Earthquake

In terms of frequency and severity, most earthquakes that struck small towns or metropolitan areas in the twenty-first century tended to be weak. For example, California was stricken by several earthquakes in the nineteenth, twentieth, and twenty-first centuries; most of them, however, did not exceed 7.0 in the Richter magnitude scale (see the article entitled *List of earthquakes in California* in Wikipedia). For this reason, the *SIO*-type earthquakes are the most common pattern of shakings in the modern world.

Although the *SIO*-type quakes frequently occur and may look harmless, they are by no means risk-free. On the contrary, they can lay a long-term or irreversible foundation for the emergence of the *SIE*-type quakes (see the Hualien earthquake above).

Since the *SIO*-type earthquakes are enormous in quantity and similar in intensity, finding a "typical" or "outstanding" example for this category of seismic activities is extremely difficult and therefore impractical.

SUE-Type Earthquake

In comparison with the six categories of earthquakes examined in the previous pages, the *SUE*-type quakes might look "far less threatening" because of the following factors:

First, compared to the major earthquakes addressed in the previous pages, the *SUE*-type quakes are significantly weaker because they do not surpass 7.0 in the Richter magnitude scale. In addition to low intensity, the *SUE*-type quakes do not strike human communities. Instead, these secondary quakes concentrate in unpopulated regions like deserts, tiny volcanic islands, high mountains, or wastelands.

While the *SUE*-type quakes may look "less dangerous" than major earthquakes as well as the *SIE*- and the *SIO*-type shakings, they are still seismic activities of some importance. That is, the *SUE*-type quakes can become critical events if they trigger catastrophic outcomes – in other words, the *SUE*-type quakes play the role of "catalytic agents" (or initiator) in terms of "waking up" a major earthquake. Because of this role, the *SUE*-type quakes can induce a major earthquake to strike a city. The latter, in turn, can bring severe and extensive damages to a city, particularly infrastructure breakdown.

The *SUE*-type quakes can be caused by natural factors (e.g., volcanic eruption) or artificial reasons (e.g., nuclear test). Regardless of this, the chain relationship between the *SUE*-type quakes and major earthquakes appears to remain unclear. Before this relationship is fully clarified by seismologists, finding an illustrative case for the *SUE*-type quakes seems unlikely.

SUO-Type Earthquake

The final category of seismic activities examined in this entry is the *SUO*-type quakes. Such earthquakes are very unlikely to attract the attention of the public because first, they do not exceed 7.0 in the Richter magnitude scale; second, they do not directly strike human settlements; and third, they do not bring any noteworthy or observable damages to a town or city.

Given that the *SUO*-type quakes are not strong in intensity and do not seem to influence any town or city, they are probably least threatening among all types of earthquakes. What should be noted is that even though the *SUO*-type quakes might be considered minor events, they may possibly evolve into the *SUE*-type quakes under certain situations. No matter whether this assumption is correct, more studies on seismic activities are, of course, needed.

Conclusion

In this entry, earthquakes are classified into eight typologies according to sociological perspective. Of these varying types, the *MIE* type is most likely to become a "criminogenic earthquake" because these seismic activities can bring tremendous damages to a large city. Such damages, in turn, can significantly weaken social control and produce social problems, such as the authorities having to take care of tens or even hundreds of thousands of people who suddenly become displaced persons. So unless those dilapidated buildings and facilities stricken by the *MIE*-type quakes (especially abandoned and evacuated ones) are swiftly repaired, these unoccupied structures usually will become ideal places for delinquent populations (or homeless persons) to engage in drug trade and other illegal activities. The same anomic (or disorganized) situation might, to a lesser extent, appear in those regions stricken by the *SIE*-type quakes.

In contrast, the *SUO*-type quakes are least likely to help hotspots of crime take shape because these secondary (or weak) seismic activities do not seem to have anything to do with human settlements.

Definition

Floods refer to rising or overflowing of water from its normal course that temporarily or permanently inundates an area that is usually dry (White 1945).

Introduction

Floods are the first kind of hazard studied in the field of disaster social sciences. White (1945) was the first to shift the scientific focus from the physical dimension of floods to the social dimension in terms of response capacity. According to Tobin and Montz (2011), a social approach to hazard studies is needed because the geophysical sciences are unable to understand the level of exposure of the people who are at risk; therefore, consideration of the social dimension of a disaster is lacking. White (1945) is credited with the disaster approach (see ▶ "Natural Hazards") that tries to define central concepts, such as disasters, risks, vulnerability, and resilience. His work challenged the idea that hazard studies are the most competent of the scientific disciplines. The geophysical focus on a specific hazard fails to investigate the multiple interactions between different processes and scales that are at the basis of the disaster (Alexander 1997; Hewitt 2014). Today, a rich body of literature focuses on social vulnerability as a key concept to discuss the root origins of floods and on the methodologies to measure it adopting a place-based approach (Box et al. 2016; Karagiorgos et al. 2016; Kuhlicke et al. 2011; Mavhura et al. 2017; Nasiri et al. 2016; Koks et al. 2015; Oulahen et al. 2015; Rufat et al. 2015; Sayers et al. 2018).

Floods are a natural component of the hydrological cycle with the potential to cause fatalities, displacement, and damage to environment and economic development (EU Floods Directive, 2007/60/EC). Today, floods are one of the most concerning natural hazards in the world; thousands of people are exposed to floods, frequently resulting in deaths and considerable economic damages (Pesaresi et al. 2017; Johnson et al. 2007). Floods have been defined in different

ways, based on different characteristics. Substantially, floods are defined as temporary inundations of areas that are usually dry. Typically, floods are caused by "(1) the overflow of inland or tidal waters; (2) the unusual and rapid accumulation or runoff of surface waters from any source; and (3) mudslides (i.e., mudflows)" (Federal Emergency Management Agency/FEMA 2018) as a consequence of flooding and are characterized by the moving of mud or earth by the water. As discussed below, climate change is contributing to the phenomenon; however, the human dimension continues to be central to its development.

Accordingly, in the next section, both physical and human factors that contribute to defining floods are discussed. In particular, there is an attempt to classify floods according to physical characteristics and a brief discussion on how climate change can affect floods' frequency and features. Then, the discussion is focused on the human dimension of floods and, in particular, on social behavior and social justice implications of such events.

Classifying Floods

There is no universal taxonomy on floods. Thus, different classifications are suggested in the literature. According to Johnson et al. (2007), floods can be defined based on their magnitude and occurrence. Several measures are used to quantify floods, including peak streamflow, rate of flow, water level increases, flow velocity, area or duration of inundation, frequency (Fischer and Schumann 2018), and severity (Kundzewicz et al. 2013; see also Kvočka et al. 2016). Other factors that influence floods are location, rain patterns, and basin catchment characteristics. A second way to classify floods is according to their main geographical characteristic, such as coastal floods and fluvial floods. Coastal floods, also known less frequently as sea floods, can be the consequence of high tides, storm surges, strong winds, and increases in sea levels. Fluvial floods, also known as riverine floods, are usually due to rainfall and snowmelt (Johnson et al. 2007; Blöschl et al. 2017). Johnson et al. (2007) referred to a third way of classifying floods, according to the time/space relationship. Accordingly, Rufat et al. (2015) noted that floods can be rare or frequent events with a long duration or a short duration. For example, flash floods, which suddenly occur in a specific area, can happen everywhere. According to the International Federation of Red Cross and Red Crescent Societies (IFRC), flash floods cannot be forecasted because of their rapid onset. Moreover, these hazards give people a very short amount of time to escape. In contrast, widespread floods follow a long period of rains or other weather phenomena, such as cyclones.

According to the Federal Emergency Management Agency (FEMA 2018) classification, shallow flooding and alluvial fan flooding are two other ways to classify flooding. The former type refers to floodings that do not exceed 3.0 ft of depth and where there are no water channeling systems; it is alluvial plains, depressions zones where they can form ponding areas, overbank and overland flows. The latter type is characterized by a high-velocity torrent flooding carrying water, rocks, mud, and debris and is typical in mountainous regions. This hazard is usually a consequence of high-intensity and short-duration rainfalls. The main physical consequences of alluvial fan flooding are erosion and sediment deposition. Recent forest fires, scarcity of vegetation, and other activities that make the slope soils unstable can have consequences on the characteristics of alluvial fan flooding. When the concentration of sediment in the flow corresponds to 20–40% of the volume, the hazard is considered a mud flow. Mud flows can have devastating effects in urban contexts, considering the velocity and their destructive potential (FEMA 2018).

Climate Change Effects on Flooding

In the last 30 years, episodes of extreme floods have occurred with more frequency and magnitude (Berghuijs et al. 2017). If it is difficult to identify the real weight that climate change has had in this change, it is expected that it

will have consequences on the future trends. According to the Intergovernmental Panel on Climate Change (IPCC) reports (2014, 2018), floods will undergo variations as a result of climate change. The predicted changes in temperatures and precipitation (e.g., Lee et al. 2018) as well as the early melting of snow and the anticipated peaks in rivers generated by glaciers melting should produce effects on frequency and magnitude of floods.

The extreme increase in the sea levels is a second relevant point to consider in relation to climate change and floods. According to IPCC report 2014, on a global scale, the trends of extreme episodes of high coastal water reflect those of the average increase in sea levels. This suggests a (highly probable) connection between the two phenomena, which is expected to continue in the future.

Floods can also occur as a consequence of tropical and extratropical cyclones. The IPCC report showed that the frequency and intensity of tropical cyclones in the North Atlantic had been increasing since the 1970s. Although the predictions of changes in intensity and frequency are highly variable on a regional basis, it is likely that tropical rainfall related to cyclones will increase with global warming. An increase in the speed of winds and the precipitation rates of tropical cyclones is expected, although this may not affect all tropical regions. The intensity of the phenomena is the most relevant aspect. In terms of extratropical cyclones, in the last 50 years, a shift toward the poles of the main extratropical cyclones has been detected for both the northern and southern hemispheres. This process is expected to continue, on average, reducing the number of cyclones at the mid-latitudes in both hemispheres.

Moreover, changes in monsoons can have implications for floods. At the moment, few studies have investigated climate change in the monsoon regions. There remains considerable uncertainty about circulation and precipitation, which does not allow for safe projections. However, the models indicate that there will be a probable increase in extreme rainfall in the monsoon regions, although not necessarily prompted by changes in monsoon characteristics and not necessarily in all monsoon regions (see, e.g., Loo et al. 2015).

Climate change is considered to have an impact on coastal areas and, consequently, on coastal floods. According to IPCC report (2014), effects of climate change are expected in terms of vulnerability of coastal areas, especially the lowlands, as a consequence of the rise in sea levels and increases in erosion. Moreover, in the absence of adaptation actions, the probability of these areas suffering negative consequences, such as coastal erosion and flooding, is high.

Floods can also result from avalanches. Changes in heat waves, glacier reduction, and permafrost degradation will have an impact on high mountain phenomena, such as slope instability, mass movements, and outburst floods in glacial lakes and rock stability (bedrock stability) (e.g., Deline et al. 2015; Stoffel and Huggel 2012; Stoffel et al. 2016). The expected effects on rainfall will have repercussions on slope movements in some areas. High mountain debris flows will begin earlier in the year due to early melting of the snowpack. The continuous degradation of permafrost and glacier retreat will reduce the stability of the rocky slopes.

About a social perspective, effects of climate change on flood features and frequency can undermine livelihood capacity especially in poor contexts (IPCC 2018; Olsson 2014). Poor people have been always more exposed to risks, as a consequence of less response capacity and marginalization. Their "confinement" in hazard-prone areas has been deeply recognized in several studies (see, e.g., Winsemius et al. 2015). Climate change is expected to increase the vulnerability of poor people as a consequence of the intensification of the episodes of extreme floods. Projections on river flood risk have been estimated (e.g., Arnell and Gosling 2016); accordingly, the episodes of current 100-year flood could double up by 2050, interesting about 450 million of people. However, the study suggests that these changes will not occur in the same way everywhere on the globe. Increases are expected in particular in tropical Africa, South and East Asia, South America, high latitude in Asia, and

North America, while decreases should take place in the Mediterranean, South West Africa, and Central Europe. Similar results have been described in IPCC reports, according to which increases in annual outflows will interest high latitudes, while reductions will occur in parts of Southern Europe, the Middle East, and Southern Africa (IPCC 2014).

Small islands states are considered to be the most vulnerable regions on the planet, and the impacts of flooding are expected to increase in these areas due to climate change. Small islands are particularly vulnerable to the average increase in sea level, since they are affected by floods, shoreline changes, and salt water infiltrations in groundwater (Kelman 2014; Mimura et al. 2007; Nunn and Kumar 2018; Ratter 2018). The contribution of the average increase in sea level to an increase in coastal high-water levels, together with the increase in the maximum wind speed of tropical cyclones, is another problem faced by small tropical island states.

While the projections (IPCC 2014) relative to the island areas differ considerably from those of the continental areas, they are characterized by considerable limitations due to the lack of data, the brevity of the observation periods, and the inadequacy of the existing climate models to represent small island territories. This is particularly evident with reference to rainfall on a global scale and with regard to the increasing number of hot days and hot nights and the decreasing number of cold days and cold nights in the Pacific and the Indian Ocean. The level of confidence for changes in the number of days/hot and cold nights is high in the case of the Caribbean, due to the greater availability of data. Changes in the oceans have repercussions on coral reefs; in particular, warming of the ocean surface has caused coral bleaching, ocean acidification, reduction of average coral growth, and reduction of oxygen concentration in the water (Seneviratne et al. 2012) with potential consequences on the flooding risk in the coastal areas.

Root Causes of Floods

According to the European Union Floods Directive (EUFD, 2007/60/EC), floods can generate damage that has important social and economic consequences for a territory. The EUFD defines floods as natural phenomena that cannot be prevented. This seems to propose the idea that there is no way to intervene except to reduce exposure. Nevertheless, the Directive recognizes that some types of human activity, such as urban planning, economic activities, hydraulic interventions, and climate change, can contribute to the impacts caused by floods. Thus, human activities can have a central role in the construction of the conditions that can lead to floods. Rufat et al. (2015) stated that several human processes form the basis of flood episodes. They include urban sprawl and, more broadly, urbanization, but also forest fires, modifications of vegetation, economic activities that destabilize the slopes, interventions of transformations and cementification on the coastline, abandonment of the slopes, no maintenance of water basins, water basin reduction interventions, destruction of natural barriers like sand dunes and mangrove forests, and granting of building abuses in areas at risk. The presence or lack of structural defenses can have a positive and negative impact on the movement of water. Moreover, aspects of social vulnerability, such as economic conditions, population distribution, and the presence of more vulnerable groups (like elderly people, persons with disabilities, low-income people, and so on), can amplify the effects of flooding and transform a hazard into a disaster.

The Behavioral Issue in Floods

During flood episodes, it is usually observed that people react incorrectly or that they are not prepared. It happens also in hazard-prone areas. Drowning is considered the principal cause of death in floods, and it is frequently consequent to wrong decisions (Becker et al. 2015). According to Becker et al. (2015), five situations induce people to entering flood waters and expose themselves to danger: undertaking recreational activities, like swimming and surfing; trying to reach a destination; recovering personal items or pets; trying to carry out work tasks; and attempting to rescue or assist

other people. These actions are consequence of risk underestimation. Thus, they are linked to personal perception of hazards.

Perception is a relevant issue in the different steps of flood risk management, from prevention to response. Misperception is usually at the basis of wrong decisions in preparedness and emergency phases. Physical and social characteristics have been analyzed with the aim of understanding which factors influence risk perception, like distance proximity to risk areas (e.g., O'Neill et al. 2016), psychological factors, socioeconomic and cultural ones, emotions and experiences, trust in institutions and rescue system (Fuchs et al. 2017; Thistlethwaite et al. 2018; also see Slovic 2016), and worry (Lechowska 2018).

According to Schad et al. (2012), misperception can depend also by a few sense of own responsibility in producing the conditions from which hazards can take place, for instance. About this, Soetanto et al. (2017) suggested that cultural, experiential, and individual factors alter the perception of social responsibility, with implications in terms of willingness to adopt resilient behaviors. A good level of risk perception does not always mean that people are willing to adopt good social protective behaviors (about this see "Risk Perception Paradox" by Wachinger et al. 2013.

Social Justice in Flood Risk Management

According to the European Commission (EC 2007), flood risk management (FRM) is the sum of all the actions taken to reduce the occurrence and impacts of floods. According to Driessen et al. (2016), studies on the topic have focused more on the natural and technical dimensions of floods. Justice is one of the topics that has received less attention (see, e.g., Johnson et al. 2007; Thaler and Hartmann 2016). Anyway, issues of social justice are central to assessing risks (Maantay and Maroko 2009). This has been partially recognized in the EU Floods Directive (2007) that refers to the need for a fair distribution of responsibilities. In scientific literature, studies of environmental justice recur in particular to the concept of vulnerability that defines who loses the most in floods and the differences in class exposure. Questions about marginalization and unequal access to security are central in flood risk management. Today, FRM must deal with the increasing exposure to flood risk and with the limits of a government's capacity to respond to these hazards. Considering the increase of the areas exposed to flood risk, political choices must be made to decide where and if interventions should occur, and the relevant implications of those decisions must be addressed in terms of distributive justice (see Johnson et al. 2007). Concept of justice differs in every country and can have different implications on the way of allocating and distributing protective solutions (Thaler and Hartmann 2016).

Measures for flood protection can have implications on the vulnerability distribution, with, e.g., consequences on the property values and on the level of exposure. These choices can be at the basis of gentrification processes (see the case of New Orleans after Katrina hurricane) and social conflicts, and they can be interpreted as violations of the social contract (Zografos 2017). The social contract bases on the idea that citizens are obedient to the state in exchange for security. So the state is asked to guarantee social security. When the condition of security is lost or is perceived as reduced or lost, in particular in case of disasters, the validity of the social contract is challenged. A discussion of the social contract may produce the loss of social control by the state and governmental inability to continue to guarantee social security for the future.

Conclusion

Floods are situations of overflowing in dry areas that can happen suddenly or slowly and with different impacts. They can be classified according to different characteristics, like magnitude, location, and impacts. Most relevant differences are identified between coastal and river floods. Climate change has been expected to have impacts on frequency and intensity of floods as a consequence of different kinds of climatic phenomena, like cyclones, rainfalls, and sea

level rise. Small islands are the most vulnerable areas exposed in particular to sea flooding.

The origin of floods usually can be traced to human interventions that altered the natural water system. Many human activities have implications on flooding occurrence, and they are responsible for disaster consequences. Also the measures adopted to reduce flood risk can have consequences in terms of vulnerability and implications for social justice.

Definition

Hurricanes and typhoons are tropical cyclones with different origins and areas of impact. They are meteorological natural disasters that have significant impacts, could have cascading effects, and could be exploited for terror purposes.

Introduction

Hurricanes, cyclones, and typhoons in the context of security and emergency management go beyond a simple definition. They must be looked at not just from the physical characteristics and potential devastation, but holistically with regard to cascading events, resiliency, and homeland security impacts.

Simply, *hurricanes* are tropical cyclones that originate in the Atlantic Basin (typically the Atlantic Ocean, Caribbean Sea, and Gulf of Mexico) and the eastern and central North Pacific Ocean. *Typhoons* are tropical cyclones typically in the Northwest Pacific. *Tropical cyclone* nomenclature is typically used for storms that are in the South Pacific and Indian Ocean. Hence, geographical location determines what the storm is called (NOAA 2018). They are categorized by wind speed via the Saffir-Simpson scale ranging from Category 1 storms with sustained wind speeds of 74–95 miles per hour (MPH) to Category 5 (157 MPH or higher). (The Saffir-Simpson hurricane wind scale is based on a hurricane's sustained wind speed that reflects potential property damage and is categorized as major (Category 3 and higher) because of the potential for significant loss of life and damage.) Category 3–5 storms are considered major (NHC 2018). Table 1 is a graphic representation of the Saffir-Simpson scale showing damage potential.

Whether a hurricane or typhoon, the storms are rotating low-pressure systems containing thunderstorms with no clear delineation between the air masses. They start as tropical depressions with wind speeds of less than 39 MPH. They

Natural Hazards: Hurricanes, Cyclones, and Typhoons, Table 1 Saffir-Simpson scale

Category	Sustained winds (MPH)	Wind damage
1	74–95	Very dangerous winds producing some damage
2	96–110	Extremely dangerous winds causing extensive damage
3	111–129	Devastating damage will occur
4	130–156	Catastrophic damage will occur
5	>157	Catastrophic damage will occur

Source: (NHC 2018)

become tropical storms when wind speeds exceed 39 MPH but are less than 75 MPH, when the storm becomes a hurricane, typhoon, or tropical cyclone.

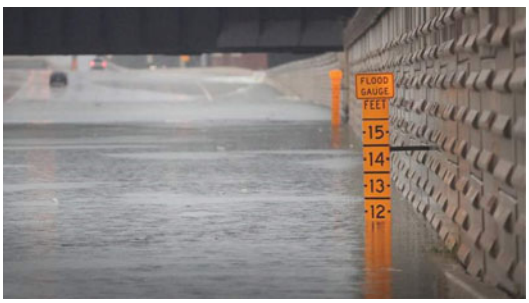
Characteristics

These storms are characterized by wind, rain, storm surge, and flooding, all of which cause damage. The wind causes damage to structures and frequently causes widespread power outages. Wind and the width of the wind field is a factor in storm surge and causes additional damage, such as that experienced with the 2005 Hurricane Katrina levee failures. Rain and flooding, as experienced with Hurricane Harvey in Texas in 2017 with its more than 50″ of rainfall, resulted in the failure of the Addicks and Barker dams, which are flood control structures located in the City of Houston (Rogers 2017). The dam failures, like other similar rain and flooding events, could cause extensive damage, casualties, contamination of drinking water, and a range of environmental issues.

The effects of wind as measured by the Saffir-Simpson scale includes estimates of expected damage. For example, a Category 2 hurricane with winds of between 96 and 110 MPH can be expected to cause extensive damage. This equates to well-constructed homes sustaining major roof and siding damage, shallow-rooted trees could be snapped or uprooted, and numerous roads could be blocked (NHC 2018). As we have seen from Hurricanes Irma and Maria in Puerto Rico in 2017, extensive and lengthy power outages can result.

The effects of hurricane, typhoon, and tropical cyclone rains are dependent on many factors. Rain, when considering intensity and surface conditions (soil and imperviousness) when combined with wide wind fields and storm surge, can cause extensive flooding. The impacts are at the mercy of the intersection of the built and natural environment and could cause both personal and economic impacts. Drainage and flood control structures, such as levee walls, seawalls, and dams, are important in mitigating the impact of rain, storm surge, and flooding. What and how one builds in flood-prone areas is important. In Houston, for example, many highway underpasses are depressed; hence they flood easily. (It is standard and widely accepted civil engineering practice to elevate or depress road crossings at a major highway. This is because local and regional/county roads often predate the major highway. Adjacent land use, topography, soil conditions, water table, and construction costs are among the factors that "drive" the elevation of the major highway, its entrances and exits, and whether or not the crossroads are elevated or depressed. In Houston, these conditions are prevalent requiring the depression of many crossroads, highway entrances and exits, and turnarounds. This condition is not unique to Houston and can be found throughout the country.) The photo below in Fig. 1 shows how that when the elevation under the highway must be depressed, the general public can be made aware of the potential flooding with the associated danger.

There is much discussion that there is a link between global warming and more frequent and stronger hurricanes. Global climate models suggest that greenhouse gases can cause ocean warming, but observational data suggests that the warming may not be as extensive as suggested (Landsea 2011). Hurricanes, typhoons in the Northwest Pacific, and severe tropical cyclones in the Indian and Southwest Pacific have been destructive and responsible for mass casualties and extensive property damage. Landsea suggests that ocean temperature is not the only factor that



Natural Hazards: Hurricanes, Cyclones, and Typhoons, Fig. 1 Typical Underpass Flood Cage. Source: (Cleary 2017)

causes disturbances to become tropical storms, hurricanes, and typhoons. Moist air, thunderstorms, and wind shear are also contributors. Climate models posit that there is a 2-degree warming of the air for every degree of ocean warming (Thomas Knutson 2004).

How does this affect hurricanes, typhoons, and tropical cyclones? Modelling suggests that hurricanes, typhoons, and tropical cyclones may be slightly stronger by the end of this century. Moreover, the climate models also suggest that the number of tropical storms, hurricanes, typhoons, and tropical cyclones will not go up and may perhaps even decrease, which could be attributed to wind shear.

What does this mean today? With the predicted 1°F increase in ocean temperature, hurricanes, typhoons, and tropical cyclones may experience a similar increase in intensity. Using the Saffir-Simpson scale, a Category 5 hurricane would produce a 1–2 MPH increase in wind speed. Landsea opines that hurricanes, typhoons, and tropical cyclones are stronger due to global warming, but it is inconclusive as to the magnitude. A 1–2 MPH increase in intensity is small and not measurable by aircraft and satellites (Landsea 2011).

Landsea further states that it is not surprising that many have concluded that damage and losses are comparable to the anticipated rise in ocean temperature. However, this is not necessarily the case and does not consider other factors that cause damages. Two of these include (1) people have more money now than in the past resulting in more expensive housing and personal property and (2) that people choose to live near the coast. What does this mean? People are willing to accept risk, but preparedness, mitigation, and forecasting and tracking can offset that risk.

Hurricanes, Nor'easters and Winter Storms

Hurricanes can occur in many forms and include a combination of weather patterns and events to create unique storm events year round (Pereria 2018). They include:

- *Bomb cyclones* or *bomb*s, which are characterized by the rapid intensification of a cyclone far offshore with or without heavy snow.
- Winter hurricanes, which are *extratropical cyclones* outside of the tropics, but are simply a winter storm that may have hurricane winds offshore.
- *Nor'easters* are storms that run up the East Coast with maximum intensity impacting New England and the Canadian Maritime Provinces.
- *Blizzards* are winter storms with tropical storm winds lasting for a period of 3 hours more.

Hurricane or Superstorm Sandy, for example, was a meteorological anomaly and special type of storm. It wrapped cold air around an intact, tropical warm core and has been considered to be the combination and confluence of a hurricane and Nor'easter resulting in extensive and widespread damage in the Northeast (Halverson 2013).

Over a 3-week period in February and March 2018, four consecutive Nor'easters impacted the Mid-Atlantic and Northeast states. These storms were characterized by high winds, heavy snowfall, and extensive coastal flooding. Extensive and prolonged power outages were experienced, which could have been exploited by those seeking to increase the devastation for terror purposes. These storms are typical of Northeast winters, but the intensity, frequency, and timing were significant. Research is being conducted to examine the storm events and trends (Liberto 2018).

What Are the Natural Impacts?

Hurricane, typhoon, or tropical cyclone damage is not only from wind. It occurs as the result of, among other things, rainfall, storm surge and flooding, and resulting impacts. Storm surge and flooding post Hurricane Katrina in 2005 combined with pollutants from, among other things, chemical plants and waste water treatment facilities was thought to have created a "toxic soup." However, research by Louisiana State University, the Louisiana Department of Environmental Quality and American Chemical Society, found that the floodwaters were not nearly as toxic and

concluded that it was more like drainage experienced after a heavy rainfall (Marris 2006).

Hurricane Harvey in 2017 caused extensive flooding in the Houston metropolitan area associated with a 50″ rainfall over several days. Dam releases, much like the failure of the levee walls in New Orleans during Hurricane Katrina, were a major source of devastation exacerbating the extensive rainfall and storm surge. So, the failure of constructed facilities can worsen the damage directly attributable to wind, rain, and flooding associated with a hurricane, typhoon, and tropical cyclone.

Forecasting and Tracking and Preparedness

Forecasting and tracking and preparedness measures are key factors that reduce risk and, ultimately, loss of life and damage. As was seen with the recent preparation for Hurricane Florence (occurred during mid-September 2018), people are given ample time to prepare their homes and business and evacuate to a safe location. You also see government agencies and volunteer organizations stage and safely preposition assets to immediately assist in the response. Power companies and other utilities also stage repair crews and prepare their facilities to minimize damage and recover as soon as feasibly possible. Forecasting and tracking and preparedness have come a long way since Hurricane Katrina.

Forecasting and tracking is not just from the National Hurricane Center but comes from independent weather companies, such as The Weather Channel, the meteorology departments of major research universities, and local and national television companies. The use of aircraft and satellites has helped by providing visual and electronic data that is used in the forecasting and tracking. A range of different computer model developments has dramatically improved research and forecasting activities.

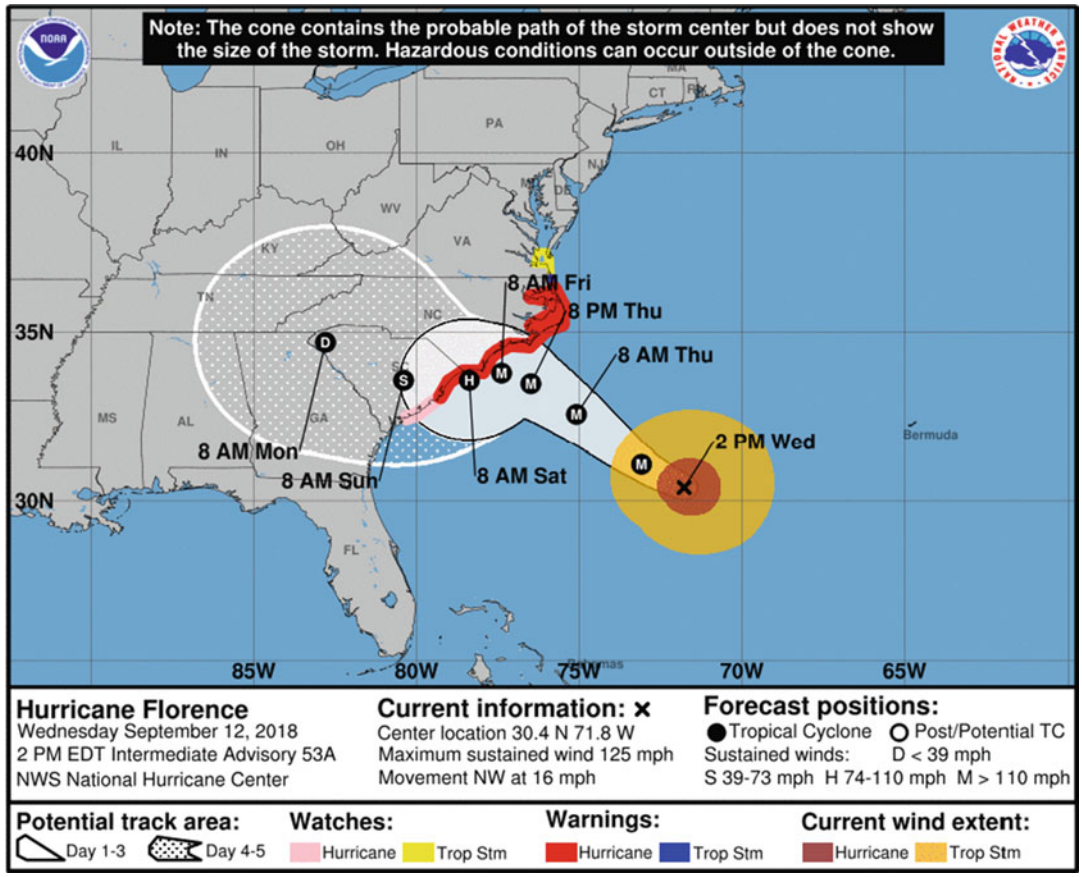
There are several kinds of forecast models. *Dynamic models* look at the physics and motion of the atmosphere, while *statistical models* are based on past hurricane data. These models can be blended into *statistical-dynamic models* that use historical data from both storm behavior and atmospheric variables to develop forecasts. *Trajectory models* move a hurricane, typhoon, and tropical cyclone along a forecasted track based on the wind field. *Ensemble models* use forecasts from different models, physical conditions, and/or initial conditions to create a blended forecast. *Numerical models* of storm surge, waves, and coastal flooding are used to forecast landfall impacts, rather than track and intensity (University of Rhode Island 2018).

Research models are designed to simulate the behavior of a hurricane, typhoon, and tropical cyclone but are not necessarily intended to make forecasts. These models are generally more complex and data intensive than *forecast models*. *Research models*, however, have been known to be used to forecast hurricanes, typhoons, and tropical cyclones or improve on existing models. Hurricane research and *forecast models* are focused on making the 3–5-day forecasts in addition to, along with climate models, predicting future hurricane activity (University of Rhode Island 2018). Figure 2 is a forecast track with cone of uncertainty that is typically used during the preparedness phase.

Cascading Impacts

Cascading events occur as a direct or indirect result of a man-made or natural disaster (FEMA 2013). Power outages caused by hurricanes, blizzards, or earthquakes are examples of cascading effects. An oil spill caused by a truck accident on an icy road during a winter storm is another. *NaTechs* (Natural and technological disasters) are those cascading events whereby a natural disaster causes a technological disaster (Brenda Phillips 2017).

A classic example of a disaster with cascading effects, the Fukushima Daiichi nuclear power plant disaster in 2011 is a common example of a NaTech. The disaster is the result of an earthquake in the Pacific Ocean that caused a tsunami that disabled the emergency generators resulting in a failure of the ability to cool the reactors. A power outage resulting from a hurricane, typhoon, or blizzard is a cascading event and is considered a NaTech by many. A difference, however, is that damage to power distribution systems from a hurricane, typhoon, or blizzard is



Natural Hazards: Hurricanes, Cyclones, and Typhoons, Fig. 2 National Hurricane Center Forecast Track Example. Source: (NWS 2018)

expected, but a Fukushima Daiichi disaster is not (communications and power outage, although technically NaTechs, by definition, are expected results of certain disasters (e.g., Nor'easter and hurricane) and are predictable consequences. NaTechs can be considered as aberrations and not an expected result of a natural disaster. The Fukushima Daiichi nuclear power plant catastrophe (earthquake, tsunami, and power plant disaster), for example, was an unexpected event commonly thought of as a NaTEch.).

Some say that power and communications outages are NaTechs. From the perspective of cascading events or anticipated results, they are expected and are not a low likelihood event like the Fukushima Daiichi disaster. Consider, for example, the 2018 late winter Nor'easters or even the 2015 snow season in the Northeast, which resulted in extensive power outages, but it was expected, and resources were staged so as to respond as soon as possible. Metropolitan Boston, New Orleans, Houston, and South Carolina should now be considering power outages a cascading effect from a hurricane or tropical storm and resulting storm surge and flooding.

Let's look at Hurricane Harvey in 2017. This Category 4 hurricane was quickly downgraded to a tropical storm after landfall. Given its location and hurricane experience, Houston prepared for the storm, but the prolonged rain and extensive flooding was not anticipated. Because of the heavy rains, Barker and Addicks reservoirs, which are used to control flooding in downtown Houston, had to have controlled releases causing

damage downstream (Rick Jervis 2017). Similar scenarios were experienced with the levee failures from Hurricane Katrina in 2005 – such eventualities should be considered during planning, mitigation, and preparedness.

What Are the Security Concerns?

When considering and preparing for hurricanes, the focus is on safety and preservation of life and property. But the protection of people and property from the exploitation of a natural disaster must also be considered. A terrorist could target the evacuees and first responders, among others, as they flee from or respond to a natural disaster. Not just people, the objective could be a business or government agency being targeted for sabotage. For example, as Hurricane Rita approached Texas, the Department of Homeland Security (DHS) received an alert of a potential attack on railcars containing hazardous material along the Gulf Coast when everyone was otherwise hunkered down. A successful attack could have been clearly catastrophic exacerbating the impact of the hurricane. Fortunately nothing occurred.

Some other security considerations associated with hurricanes, typhoons, and tropical cyclones involve power outages, loss of communications, compromised access via road and bridge outages, and environmental problems. With regard to power outages, access and perimeter control could be inoperable unless an alternate power supply is readily available. This is important at transportation facilities and, in particular, airports. Communications systems are dependent on power. Even with power, they could be impacted resulting in the inability of alarm systems to operate. In addition to airports, other infrastructure has alarm systems not the least of which is the nation's nuclear power plants. Other potential exploitations might occur when there is no power or communications, such as the potential interdiction at a water treatment plant to contaminate the water supply, introduction of a bio/chem agent in an out of service transportation terminal, such as South Station in Boston, and placing an improvised explosive device (IED) in a major hospital emergency room. These were scenarios considered during and after Hurricanes Katrina, Rita, and Ike.

With roads and bridges out, a terrorist group could conduct an active shooter event or explode an IED at many venues, to including an evacuation shelter, with the knowledge that law enforcement and first responders may not be able to respond quickly. It is a time when everyone is focused on the immediate protection and saving and preserving life and property from the hurricane, typhoon, or tropical cyclone. The range of environmental issues can include an oil spill resulting from storm surge and flood waters and overflow of a chemical plant or wastewater treatment facility. If the disaster does not do this, then a terrorist could take advantage of conditions and manually open oil, sewer, and/or chemical plant lines.

In the above potential scenarios, what may have been considered a hardened target may now become a soft target. This concept can be applied to any infrastructure and operating system post landfall.

How to Prepare and Mitigate

The issue with hurricanes, typhoons, and tropical cyclones is the intersection of the built environment and nature that creates the disaster. Development on the coast, in flood-prone areas, and along estuaries creates the intersection. We, as a society, enjoy living near the coast and accept the risk. Mitigation measures are the responsibility of not only government agencies, but that of the home and/or business owners. Structural and nonstructural measures are the methods of mitigation that are the most prevalent.

Structural mitigation measures include, at the government level, levee walls, seawalls, and storm drainage systems. These also include resilient structures that provide municipal services, to include power, water, and waste water treatment. For a building or homeowners, this means designs that have floor elevations above flood level, stable roofs (via "hurricane clamps"), and resilient foundations and structures.

Nonstructural mitigation measures at the government level include zoning ordinances and building codes that restrict where and how to build

and acquiring land susceptible to flooding by eminent domain. Home and business owners can mitigate the effect of hurricanes, typhoons, and tropical cyclones by using flood zones as parks and parking areas, flood insurance, and voluntary relocating out of hurricane and storm surge-prone areas.

Conclusion

When considering hurricane, tropical cyclone, and typhoon preparedness, an all-hazards approach needs to be taken. Such includes the protection of life and property and the protection of the evacuees and first responders from cascading affects and exploitation. Therefore, emergency managers and professionals should not just consider the hurricane, tropical cyclone, or typhoon at hand, but need to consider what could happen after landfall. They should prepare for cascading events so that a Fukushima Daiichi does not happen or a potential exploitation like that which could have occurred along the Gulf Coast as Hurricane Rita approached can be avoided.

Power outages are common with many of these storms, and approaches to minimizing them should be a major focus. Infrastructure resilience and proper mitigation measures are important. Presidential Policy Directive (PPD) 21 identifies the power or energy sector as critical because it is an "enabling function" across all of the 16 critical infrastructure sectors (Energy Sector 2018). Without power or energy, response and recovery is made significantly more difficult.

Natural Hazards: Pandemic Threats by Infectious Diseases

Peter Mameli
Public Management, John Jay College of Criminal Justice, New York, NY, USA

Keywords
Center for Disease Control · Disease outbreaks · Global health · Infectious diseases · Plague · Public health · WHO/World Health Organization

Definition

Human hazard: Threats to human populations where the authentic source of the occurrence is technological or human made.

Natural hazard: Threats to human populations where the authentic source of the occurrence is found in the natural world. Biological natural hazards include the ecological emergence of infectious disease.

Pandemic: The global outbreak of an infectious disease where no vaccine, or natural resistance, exists that is able to stabilize the threat.

Introduction

In 2018 the World Health Organization (WHO) identified a group of priority diseases and pathogens for research and development purposes in the years ahead. Each one represents a unique threat to public health, although it cannot be said with certainty that large-scale outbreaks will necessarily occur. These threats either have no current countermeasures or countermeasures that are known to be lacking for preventing spread of illness. The list included Crimean-Congo hemorrhagic fever (CCHF), Ebola virus disease and Marburg virus disease, Lassa fever, Middle East respiratory syndrome coronavirus (MERS-CoV) and severe acute respiratory syndrome (SARS), Nipah and henipaviral diseases, Rift Valley fever (RVF), Zika, as well as Disease X (World Health Organization 2018a).

Disease X holds a special place on the list, for it reflects an understanding that catastrophic infectious diseases are far from comprehensively identified at this point in time. As such the possibility of new pandemics emerging is not far-fetched, but quite conceivable.

There has been disagreement about what the term "pandemic" should encompass for many years. One concise definition posits that a global outbreak of a novel disease is necessary to invoke the word (World Health Organization 2010). Less compact explanations suggest pandemics involve countrywide spread at the very least or consider regional impact on one or more continents as acceptable for the term to be applied. In any nuanced discussion, case levels are usually seen as being considerable, and immunity limited. For the purposes of this submission, the World Health Organization approach offered above will be employed. As a result of accepting this definition, the review to follow keys more on international, rather than regional, national, local, and individual approaches to these types of public health threats.

New pandemics are not the only health concerns people around the globe must remain vigilant over, however. The reemergence and tenacity of plague in disparate locations around the globe, as well as continuing battles with HIV/AIDS and new strains of influenza, are but three established infectious diseases that stubbornly stalk human populations. Further still, there remains a seemingly relentless nature to illnesses such as tuberculosis, malaria, yellow fever, cholera, syphilis, and gonorrhea. Combined with the steady onslaught of a range of slow-acting chronic diseases, global public health crises of all kinds promise to continually impact

and even shape the course of human development as time moves on. Pandemic threats are simply one type among them.

Although not the focus of a piece on natural pandemic threats, due to the technological or human-made intervention that leads to their spread, the ongoing specter of biological warfare or terrorism releasing some uncontrolled deadly pathogen on the planet must at least bear mention in this discussion. In addition industrial accidents also present the human population with an array of outbreak possibilities, both at the time of occurrence as well as during the aftermath of crisis. Recognizing the full breadth of infectious disease threats that can become global is important because innovations from responding to each type can feed into an overarching approach of reinforcing techniques for addressing pandemic emergencies, in general.

To some, historically, we have been poorly prepared to deal with the global impact of many or all of these illnesses. To others, the reality of drug resistant, emerging and re-emerging infectious disease has been a spur to action that has led to the creation of rapid response units and global detection systems. To capture a snapshot of the current picture on these matters, this contribution will address how handling biological natural hazards involving infectious disease pandemic threats are best managed through a dynamic coupling of players across a range of response levels and sectors of action.

Background and Context

Ancient African, Asian, and European pandemics provide examples that catastrophic illness has been with us for as long as we have been recording human societal development. While it is difficult to say whether or not a new pandemic will have the same enormous impact on civilization that many feel the plague of Europe did in the fourteenth century, or the 1918 avian influenza outbreak did in the early twentieth century, it is at least clear that the study of pandemic management offers an opportunity to evaluate and reflect on the current state of public health system administrative progress. Effectively responding to these threats is a complicated process that requires unusual amounts of cooperation and coordination to be successful.

As should be clear from the discussion to follow, pandemic threats require treatment from the international level to the regional, national, local, and individual ones (see chapter on ▶ "Emergency Management: International"). From global planning to local implementation, coherent and cohesive action must be closely knit together to accomplish pandemic infectious disease management. In addition, differing sectors of society concerned in this type of process must be involved in coordinated action to gain the most from such preparations. While the health sector is clearly central in such a discussion, it does not exist in a vacuum. Technological advances, as well as the contours of the legal, criminal justice, social, cultural, economic, and political sectors, also hold sway on what can and cannot be done. And, with so many infectious diseases emerging directly from the natural environment, expertise and leadership from within the ecological sector is also important to leverage when describing and explaining problems, as well as crafting policy responses.

The range of players involved in such a task spans governmental, nongovernmental, and private domains, with representatives from each needing to navigate the web of interaction in order for crisis engagement to be effective. From international policymakers to on-the-ground first responders, these actors can be involved with multiple levels of response and sectors of impact or be isolated within a particular level and sector alone. Collectively organizing their actions smoothly is one core goal of pandemic management.

A defining characteristic of pandemic threats in the twenty-first century is the impact that processes of globalization have had on the ability of pathogens to spread. Advances in the movement of people, animals, and goods have accelerated the dissemination of infectious agents. As such, the context of understanding pandemics needs to be viewed through an arc of time that encompasses improving technological innovation. Today's problems require

the reassessment of quarantine strategies, engaging emerging technologies, understanding the differences faced from rural and urban outbreaks, and many more subject areas.

Human-made events, where the goal is political destabilization and change, warrant note here as well because they highlight some important effects sought from deliberately created health calamities. These are valuable concerns to include because the results are not unique to human-made crises of this type. Natural pandemics can also give rise to significant political upheaval and security concerns. The result in both cases can be the weakening of policy and cultural bulwarks, leaving room for unrest and violence to emerge.

Understanding that these issues are often addressed within pandemic threat situations provides us with a broad overarching rationale for continually assessing our collective and ongoing effort to improve the ways that we approach these hazards. Assuring that both cases and death tallies are minimized are not the only values at stake.

Planning for Naturally Occurring Pandemic Threats

Preventing future pandemic public health emergencies, or minimizing their effects during response, requires establishing health regulations and legal rules that provide ways to clearly prepare, assess, and respond to a crisis. Such conventions enable the identification and containment of risk, as well as focused and concerted action in redressing danger. These platforms then allow for sequential planning, performance measurement, and evaluation of programs as essential aspects of managing these types of events. Training, practicing, and the organization of thought and action are essential elements in this process. Applying knowledge through an "all hazards" approach to crises creates economies of scale that allow for broad-based treatment of public health threats. This systematic application of routines makes the most of generalized information while addressing the unique concerns of certain types of outbreaks. Over time, information that is learned from on-the-ground efforts is cycled through a global system of feedback and refinement.

Infectious disease pandemic threat preparations can be examined within such conceptualizations. The ongoing concern about potential flu pandemics lends itself to displaying how accepted approaches to public health pandemic management fan out from global bodies to regional ones and then to states and localities. The cycle of information sharing is not a one-way street, however. As events occur that reinforce or add to the knowledge base, it is hoped all actors in the system will update their plans in accordance with lessons learned from throughout the system.

Illustrating policy diffusion of this nature can be quickly demonstrated through the highlighting of documents offered across different levels of the international system. For example, WHO provides a "checklist" to states, governments, and health authorities readying themselves for a possible influenza pandemic (World Health Organization 2005, 2018b). WHO addresses areas of relevance for pandemic management that spans topics from preparation, to surveillance, to case treatment, to community engagement, maintaining services, carrying out research, and finally implementation within its list categories. Other levels of response engage in similar activities. Some examples are provided below.

At the regional level, the European Union provides guidance to member states through the European Centre for Disease Prevention and Control's publications on national influenza pandemic plans that is no less thorough than those of WHO (European Centre for Disease Prevention and Control 2018). The United States Department of Health and Human Services presents a national influenza pandemic plan that serves as one model for addressing a flu-based scenario (United States Department of Health and Human Services 2017). All actors operate with a reasonably common vision that is steeped in experience from treating the illness.

Where countries and local communities are concerned, governmental and nongovernmental players are best advised to craft legal, policy, and

funding instruments that will facilitate and guide response during a pandemic emergency that make use of accepted global and regional strategies but also take note of their unique settings. A wide range of legal and regulatory scaffolding exists that can be offered as examples for exploring options. All should be coordinated as best as possible with international understandings of pandemic management. Mutual aid agreements that cut across jurisdictions and localities, as well as a variety of public-private partnerships, often are useful means of providing a unified vision for how to react to such situations at the base level of communities and local governments, where the heart of the actual work fighting disease spread will take place. To the extent these efforts dovetail with the international image for redressing infectious disease spread, so much the better.

As an example of a country-level arrangement, the United States applies a comprehensive planning approach to both human-made and natural hazards that uses a variety of frameworks designed to guide the phases of emergency management at the national level. Built to maximize the logic of the all hazards model in real-world settings, and acting in concert with the National Incident Management System (NIMS), these frameworks focus on aspects of the emergency management cycle while offering perspective to how roles and tasks may dovetail across the process. Local and state American governments are engaged in their own planning activities, as well. Pandemic emergency preparation across all levels falls within this broad conceptualization of mitigation, preparedness, response, and recovery (Lindsay 2012).

Managing Naturally Occurring Pandemic Threats

As the above documents display, planning only takes preparedness so far. Ensuring effective action in pandemic response requires that the plans be tested and appraised on a regular basis, in order that weaknesses can be identified. It also mandates that lessons can be both learned from, and integrated back into, the planning cycle. Communicating strategies, training first responders, and educating civilian populations about where to find information and resource caches become important aspects of this endeavor. Examining the effectiveness and efficiency of such activities then rests on properly constructing, analyzing, and understanding performance indicators and results in relation to intended strategies, missions, and operational goals. Plans developed and left in vacuums over time risk becoming unhelpful at best or even deadly in worst-case scenarios. Of course, central to achieving these aims is establishing a secure and operational health infrastructure that can be relied upon during an emergency. As noted below, the roles of international governmental organizations, international nongovernmental organizations, and donor states take on special importance where struggling countries are concerned.

One of the most important aspects of minimizing infectious disease pandemic threats involves active surveillance and information gathering to further prevention. This is true at all levels of identification and response. As many infectious disease pathogens are of zoonotic origin, it is clear that ongoing efforts to monitor the natural environment are imperative to the quick management and response of developing crises and could be the key to preventing a local outbreak from turning into pandemic spread. The hunting of new pathogens, as well as tracking the emergence of known ones, remains critically important in controlling public health upheavals.

While some states are better prepared to carry out these activities than others due to expertise and resource availability, those in less capable positions are equally important to carrying out the overall task at hand. As such, WHO, other relevant members of the United Nations system of international governmental organizations, supporting states, and organizations from global civil society, can be found providing personnel, skills, and guidance in these circumstances when needed.

The Global Outbreak Alert and Response Network (GOARN), in effect since 2000 and supported by the International Health Regulations (IHR) of 2005, created a WHO network of partners with the

ability to coordinate and provide the delivery of needed services to locations with health emergencies (Global Outbreak Alert and Response Network 2018). A comprehensive Events Management System is managed by WHO to further serve this purpose, and its Strategic Health Operations Centre monitors a wide range of public health issues on an ongoing basis. Addressing pandemic threat from infectious disease in relevant scenarios effectively starts with gathering the data for review at the local and country levels long before pandemic intensity is reached and then analyzing results within this international structure.

Once a new threat has been identified, response and recovery actions must be quickly engaged. Cases must be treated, and, where necessary, contacts must be traced for the work of managing spread to effectively occur. If vaccines exist, and are available, they need to be dispensed to affected populations. Best practices for controlling the particular disease must be put into effect beyond vaccine protocols as well, often modifying cultural and social norms for the benefit of enhancing safety specific to a given disease's modus operandi.

Establishing the tools to handle emergency pandemic threats needs to be connected to the awareness that rapid deployment of funds and resources may be necessary, often without a great deal of warning. This fact is consistent across sectors, actors, and levels of response. However, the degree of support required from the international system will vary based on need. In the case of WHO, establishing capacity at the global level to support states suffering outbreaks and health crises has been developed through the Contingency Fund for Emergencies (CFE). CFE was started in the wake of the 2014 Ebola outbreak in West Africa and is a part of WHO's broader Health Emergency Program. While not designed for infectious disease engagement alone, the CFE allows for rapid disbursement of financial resources to targeted recipient states that are facing extreme, and often unforeseen, health challenges. This could easily be the case where the threat of pandemic spread is involved. To the extent such financial resources can be made to affected countries and regions rapidly, worst-case pandemic scenarios stand a better chance of being avoided. This new funding structure offers WHO the ability to begin its work in crisis scenarios and settings early, as well as to support state activities as soon as possible. Other fiscal and material supports from the international system of governmental organizations, states, and civil society can take longer to mobilize (World Health Organization 2017a).

Global civil society offers additional support structures to prepare for, and respond to, pandemic threats. The Global Fund, for example, provides ways for donors to directly connect with those affected by specific health crises involving HIV/AIDS, tuberculosis, and malaria (The Global Fund 2018). It expressly recognizes that building strong health systems enables wider protection against a range of infectious diseases that are already, or could turn into, pandemic threats.

In furtherance of these goals, the organization offers supporters the ability to engage in these activities as one shot or ongoing efforts. Additionally, a variety of direct relief and support services can be found in the wealth of medically focused INGOs willing to engage health crises on the ground. Groups such as Doctors Without Borders and the International Federation of Red Cross and Red Crescent Societies are among the better known of these organizations and often find themselves in the thick of the pre-pandemic fight.

Formally recognizing the existence of a pandemic threat takes place at the highest tier of the system of response, even while a disease may be progressing on the ground in local, national, and regional settings. The fact that the disease is already active requires that the central actors recognize and categorize said threat for what it is as quickly as possible. Recognition supports the plans that have been designed for response being put into action across levels of the international system. Triggering mechanisms, such as the one described below, enable rapid and efficient coordinated response from the top down rather than sluggish and confused vertical and horizontal engagement.

At the international level, the Public Health Emergency of International Concern (PHEIC)

declaration is of critical importance to combating infectious disease spread, serving as an early warning device against possible pandemic emergence. Since the early 2000s, there has been an active effort to empower WHO, through the IHR, in a way that would invigorate response to global health dangers by encouraging concerted efforts of varied players in the political arena. Among the outcomes of this pursuit has been the creation of the PHEIC declaration that the body can pronounce in reaction to significantly threatening circumstances. Driven by WHO's IHR Emergency Committee, a committee that provides advice to the director general of the organization, declarations of this nature can be used to assuage confusion and disagreement by states, intergovernmental organizations, and international nongovernmental organizations as to the extent of a particular problem. Issuance of a PHEIC declaration signifies that the body agrees a public health threat meets the following criteria:

> i: to constitute a public health risk to other states through the international spread of disease; and
> ii: to potentially require a coordinated international response. This definition implies a situation that: is serious, unusual or unexpected; carries implications for public health beyond the affected State's national border; and may require immediate international action. (World Health Organization 2017b)

Since 2007, when the IHR on this matter came into effect and formalized the PHEIC declaration as a tool WHO could utilize, it has been used on four occasions. The first involved H1N1 in 2009, the second involved Polio resurgence in 2014, Ebola in 2014, and most recently Zika Virus in 2016. The importance of the PHEIC declaration is in the ability to develop a concerted vision of a crisis that captures competing parties and viewpoints as it welds a common position together. Indeed, the role this body of experts plays in the process speaks to how actors across levels of governance can be brought into the overall process of decision-making in a respectful, and hopefully productive, manner. As such, the process of deliberation, and the declaration itself, represents a mechanism for channeling energy and ideas – creating a critical means of linking stakeholders to each other across domains and levels of response as they craft more unified policy positions. While announcing the existence of a full-fledged pandemic will come later, if required, one value of the PHEIC declaration is in its ability to begin that process as early in the term of an outbreak as possible.

Conclusion

The best prevention, when managing biological hazards that can become pandemics, is to engage the threat as early as possible. If a threat cannot be identified or stopped in the natural environment before it appears in local human communities, then it must be pursued there. If it breaks free from these surroundings to include whole states or beyond, then it must be engaged in that wider venue. Once an infectious disease outbreak is understood to be expanding to other countries, health authorities at all levels of the system must move quickly to minimize its coverage prior to it reaching worldwide levels. The overall process is one of continuous identification and response. However, the purpose of the process does not mean the earliest alerts will be taking place when the first cases of an outbreak unfold. It does mean, however, that the alerts sounded must be made as soon as possible in the development of pandemic threats. If the earliest efforts to recognize and stop infectious disease emergence fail at the local and country levels, then international dissemination of the pathogen must be flagged for response as rapidly as possible, relying on the wealth of resources and knowledge discussed throughout this contribution.

Natural hazard · Protective actions · Protective behavior · Risk communication

Definition

A tornado is a rotating wind funnel generated by very large thunderstorms called supercell. In case the wind changes direction, there is an opportunity for moist and cold air to combine forming a rotating funnel.

Introduction

Tornadoes can occur everywhere. In the United States, every year there are more than one thousand tornadoes (Haddow et al. 2014). In term of seasonality, tornadoes occur more frequently from March to August and primarily during the afternoon and evening "between noon and midnight" (Haddow et al. 2014, p. 44). In the United States, tornadoes occur more frequently in an area called "tornado alley" than in other regions. Tornado alley is an area covering several states such as Texas, Oklahoma, and Kansas. However, the number of tornadoes now occurring in the southeast, such as in Mississippi, Alabama, Arkansas, Missouri, and Illinois, is becoming frequent (Berardelli, December 16, 2018). The main consequences in this shift in tornado location are that damage is worse due to the dense population and number of trees in these areas that prevent people from spotting them on the ground. In addition, there are more frame houses in this region than in Oklahoma for instance, meaning that the homes are vulnerable (Berardelli, December 16, 2018).

Important aspects of tornadoes management involve damage measurement, risk communication (such as how do we warn the population about potential or actual risk), protective measures (e.g., actions people are required to undertake on the basis of their location), and people's behavior in responding to this threat. The following sections will discuss these points.

Tornado Damage Measurement and Wind Speed Estimates

The intensity and the impact of a tornado on both the built environment and vegetation are measured by the Enhanced Fujita **scale** (EF-**Scale**). The Enhanced Fujita scale, ranging from 0 to 5, has been adopted in the United States and Canada since 2007 to replace the Fujita–Pearson scale due to its limitations. The Fujita–Pearson scale (F-Scale) was developed to measure the severity of a tornado and to associate wind speeds to the level of damage. The Fujita scale measures damages from light to massive on an intensity scale of 0–5 and it is troublesome for all those cases in which the tornado does not cause any damage to the built environment. The Fujita scale is limited since it is difficult without a structural damage to classify the intensity of the tornado. In addition, the Fujita scale measures the tornado severity on the basis of the most severe structural damage without taking into account the resistance and quality of the affected building. It has to be noticed that, even though the Enhanced Fujita scale revised the wind speed of tornadoes, it still provides an estimate of wind speed and not a measurement. Table 1 shows the Enhanced Fujita scale with the associated description of damages, wind speed, and typical observation.

The deadliest tornado in the United States was the March 18, 1925, Tri-state tornado which encompassed the states of Missouri, Illinois, and Indiana. This tornado killed 695 people, of which 613 in the sole state of Illinois. The widest tornado ever recorded in the United States is the EF 5 El Reno tornado recorded on May 31, 2013, in Oklahoma with a 2.6-miles (4.2 km) width (The National Weather Service). To have an idea of the width of the tornado, it is useful to remember that 2.6 miles is the actual length of central park in New York City (Climate Central, May 4th 2013). The El Reno tornado showed the importance of taking into account possibilities rather than probabilities. Even though EF5 tornadoes are the most severe tornadoes, what really makes a difference

Natural Hazards: Tornadoes, Table 1 Enhanced Fujita scale

Scale	Damage	Wind speed	Typical observation
EF 0	Light	65–85 MPH	Peels surface off some roofs; some damage to gutters or siding; branches broken off trees; shallow-rooted trees pushed over
EF 1	Moderate	86–110 MPH	Roofs severely stripped; mobile homes overturned or badly damaged; loss of exterior doors, windows, and other glass broken
EF 2	Considerable	111–135 MPH	Roofs torn off well-constructed houses; foundations of frame homes shifted; mobile homes completely destroyed; large trees snapped or uprooted; light-object missiles generated; cars lifted off ground
EF 3	Severe	136–165	Entire stories of well-constructed houses destroyed; severe damage to large buildings such as shopping malls; trains overturned; trees debarked; heavy cars lifted off the ground and thrown; structures with weak foundations blown away some distance
EF 4	Devastating	165–200	Well-constructed houses and whole frame houses completely leveled; cars thrown; and small missiles generated
EF 5	Incredible	Over 200	Strong frame houses leveled off foundations and swept away; automobile-sized missiles fly through the air in excess of 100 m (109 yd); high-rise buildings have significant structural deformation; incredible phenomena will occur

are the mitigation activities, the preparedness, and response of the affected communities.

Risk Communication, Tornado Watch, Tornado Warnings, and Tornado Emergency

In the United States, the National Weather Service (NWS) is the public agency responsible for issuing severe weather forecasts to the public. To this aim, the agency designed the Severe Weather Watch/Warning System. The purpose of the severe weather watch/warning system is to alert the public to hazardous weather situations and encourage them to take actions to enhance protection of life and property, despite recognizing that the final decision falls on individuals and households (Black and Ashley 2011). In order to fulfill its mission, the NWS defines both tornado watch and warning on the basis of the level of threat posed to people and to the action to be undertaken for each case (Pifer and Mogil 1978). The watches and warning are used for a variety of hazards such as floods, hurricanes, and thunderstorm and are considered as the cornerstone of severe weather risk communication. Tornado watch means that the "conditions are favorable for the development of tornadoes in and close to the watch area. During the watch, people should review tornado safety rules and be prepared to move a place of safety if threatening weather approaches" (NWS, Glossary). Tornado warning is issued by the National Weather Service when "a tornado is indicated by the WSR-88D radar or sighted by spotters" (NWS, Glossary). Under special circumstances, the NWS also issues Tornado emergencies.

A tornado emergency is a step-up to tornado warning and it is issued for all those situations that are extremely life-threatening in highly populated areas. The reason for which tornado emergency is issued in addition to tornado warning is that some communities might be accustomed and therefore complacent to tornado warnings. The first tornado emergency was issued on May 3, 1999, during the Bridge Creek EF5 outbreak and the last to date was issued during the Lee County, Alabama, March 3rd tornado, where 23 people lost their lives. Since the first tornado emergency, a total of 129 tornado emergency have been issued.

Another way to warn population of an incoming tornado threat is through the use of sirens. However, this is not always the best way. For instance, in Hodler's (1982) study of public response to the Kalamazoo Tornado, 17% of respondents did not understand the meaning of the warning siren that was sounded in order to warn citizens of potential danger, despite the fact that the sirens were tested every month. Other factors impacting people's understanding of warnings includes the amount of information conveyed through a message (DiGiovanni et al. 2002), the amount of time spent living in a specific area (Haas et al. 1977; Foster 1980; Perry and Greene 1983; Perry and Lindell 1986; Blanchard-Boehm 1998), and sociodemographic characteristics. For instance, the content of the warning can be misunderstood because of cultural or language barriers (Aguirre 1988), or because of the use of technical terms such as the use of probability to refer to the occurrence of a tornado (Morss et al. 2010) and some scholars have even suggested that terms such as watch and warning may contribute to a lack of understanding (Powell and O'Hair 2008; Donner et al. 2007).

Protective Action

The protective actions to be undertaken by people in the affected area in case of a tornado warning depend on one's location. If at home or in a business, the safest place to be according to Federal Emergency Management Agency (FEMA) are safe rooms and ICC 500 storm shelters, if either of these have been installed. Safe rooms and ICC 500 storm shelters are particularly recommended for those areas often affected by tornadoes such as those located in a "tornado alley." In absence of a safe room or ICC 500 storm shelters, the most interior windowless room located at the lower level of the house, such as a closet or a bathroom or a basement, are preferred. It is important in all of these situations to get additional protection through the use of

mattresses and blankets which serve to cover residents in order to mitigate the effects of flying debris. If in a car, the best thing to do pull off the road and try to reach safe shelters; if this is not possible, the next best option is to lie in a ditch face down with one's head covered by both hands.

However, the choice of which protective action to undertake can also be confusing for the population under warning in case of overlapping hazards. For instance, during the 2017 Hurricane Harvey in Texas, the NWS issued several overlapping tornado warning and flash flood warnings. The protective actions in case of flash flood warning (i.e., get to higher ground) are the opposite to those in case of a tornado warning, the latter of which required people at home to go to the lower level (Evans 2018).

Conclusion

In conclusion, tornadoes are a complex natural hazard which varies in intensity and therefore in loss of lives and properties. While, in the United States, there are some areas such as the tornado alley that are more tornado prone than others, even less prone states or states which usually are affected by less intense tornadoes should be ready to prepare for, heed the warning, and undertake protective actions. Particular attention should be posed at the understanding of warning terms such as tornado watch and tornado warning in conjunction with the potential existence of disaster subcultures.

This tornado was particularly remarkable not only because of its width, but also because storms do not usually travel from west to east.

Natural Hazards: Tsunamis

Lucia Velotti
Department of Security, Fire and Emergency Management, City University of New York (CUNY), John Jay College of Criminal Justice, New York City, NY, USA

Keywords

Vertical evacuation · Tsunami · Natural hazards · Hazard mitigation

Definition

A tsunami is a "big wave" or a series of waves that can be triggered by earthquakes, landslides, mudslides, and volcano explosions (Godschalk 2007; Haddow et al. 2013; Mileti 1999).

Introduction

A tsunami, or "big wave," can be triggered by an earthquake, landslide or mudslide (Godschalk 2007; Haddow et al. 2013; Mileti 1999), and volcano explosions. An example of a tsunami generated by landslide is the 1963 Vajont dike tsunami in Italy. The 820 feet high wave was generated by a landslide into the lake which then overtopped the dike. The wave submerged several villages in the valley leaving 1905 people dead. Tsunami can also be triggered by volcanoes. Examples of tsunami generated by volcano can be those generated by the Stromboli, in Italy, in 1919, 1956, and 1930.

Nowadays, the kind (type) of tsunami best known by the general public is the tsunami triggered by earthquake such as the 2004 Indian Ocean tsunami and the 2011 Japanese Tohoku earthquake/tsunami. Unlike other hazards, such as hurricanes, tornadoes, and earthquakes, tsunamis do not have a scale to measure their intensity or their ability to create damages. However, when triggered by an earthquake, tsunamis can be classified as near-source, medium-source, and far-source-generated (Godschalk 2007; Haddow et al. 2013). The nearer the source that generates the tsunamis, the lesser the time available for people to undertake a protective behavior such as evacuating to higher ground or further inland. For instance, a near-source-generated tsunami would leave people anywhere from 5 to 20 min to undertake protective action, while a far-source-generated tsunami could leave up to 6 or more hours to reach the shore. A tsunami hazard is also a complex hazard to plan for. Complexities in planning for tsunamis are due to the presence of two hazards, the earthquake and the tsunami, and the interaction of these hazards with the human settlement or hazardous sites and other hazards such as landslides. Tsunamis can be deadly and expensive. For instance, the March 2011 Tohoku earthquake (Japan) caused the death of 15,891 people (Oskin 2015) and an estimated 309 billion dollars in property damages. However, the deadliest earthquake/tsunami, in recent times, was the 2004 Indian Ocean tsunami with a death toll of approximately 300,000 (Fritz et al. 2006).

The threat of tsunami in the United States is concentrated in the West Coast of the country, particularly in the coastal areas of Alaska, Oregon, Washington, and part of California as a consequence of the Cascadia subduction zone (CSZ). The East Coast of the United States can also be at risk of tsunami (Seismological Society of America, April 19, 2013).

The last CSZ earthquake-triggered tsunami occurred in 1700. This event is comparable to the 2011 magnitude 9.0 (Richter scale) Japanese Tohoku earthquake and tsunami and the February 27, 2010M 8.8 earthquake and tsunami in Maule,

Chile (CREW 2013). The chance of a magnitude 9.0 (Richter scale) earthquake occurring along the CSZ within the next 50 years is 10% (CREW 2013). Further, a tsunami triggered by an earthquake in the CSZ will give the inhabitants of the proximate coastal areas a lead time of between 15 and 30 min to look for safety. Different means of overcoming the threat are being contemplated based on the estimated arrival time of the tsunami wave, proximity to high ground, and population demographics. In the United States, it is assumed that people in areas with a nearby high ground will easily reach safety by going to high ground, reaching at least 100 feet of elevation, or going 1 mile inland (FEMA, March 18, 2013). Going to higher ground might be particularly challenging or people to gain safety by reaching higher ground, the fact that not everyone will be able to reach higher ground in time. This is particularly true in the case of vulnerable populations such as the elderly, people with reduced mobility, and tourists who might be unaware of the surrounding area. In addition, time to reach safety is calculated at the individual level, rather than the time it takes to evacuate in groups, as is the case for evacuating families (Velotti et al. 2013). Thus, in preparing communities for tsunami emergency, managers and public planners face several challenges.

Tsunami Hazard Mitigation Measures

Hazard mitigation by definition is made up of two main goals: reducing and minimizing loss of property and reducing and minimizing loss of lives. A general classification of hazard mitigation measures is based on the presence of engineering intervention in structural or nonstructural measures (Rossi et al. 1982; Tierney 1989). Structural measures rely on the use of engineered interventions to reduce the impact of a hazard, while nonstructural measures do not. A more thorough description of mitigation measures provided by FEMA associates hazard mitigation goals to mitigation strategies. FEMA identifies five main mitigation goals: (1) property protection, (2) prevention, (3) public education and awareness, (4) critical facilities protection, and (5) structural projects. Each of the mitigation goals and related mitigation strategies are described below. While these are general mitigation measures, the examples used will refer to tsunami hazards.

Prevention measures are aimed at minimizing the impact of a tsunami in terms of loss of life, primarily by reducing the density of occupancy in tsunami inundation zones, especially for tsunami run-up areas. Prevention measures mainly refer to land use management such as open land development regulations, planning and zoning, and open space preservation. For example, open space preservation refers to the maintenance or to the conversion of specific at-risk areas to parks or agriculture land.

Property protection measures such as acquisition, relocation, and rebuilding can also be used as mitigation measures in order to protect critical facilities (e.g., hospitals, emergency operation centers [EOC], schools, and so on). Property protection measures are very effective (Berke and Beatley 1992), but they are also among the most expensive mitigation strategies (Rossi et al. 1982). Acquisition relates to the purchase of a building or an area that is considered under threat, usually by a public entity. Once the site is purchased, it is no longer possible to build anything on it. Acquisition is generally followed by relocation and therefore rebuilding. For example, if a school lies in a flood or tsunami inundation area, the land on which the school is built can be acquired and the school relocated and rebuilt in a safer area.

Public education and awareness include those activities aimed at improving the chances of survival and people's self-reliance in an attempt to lessen their vulnerability and keep hazard awareness high. Mitigation actions that can be undertaken in this category are the production of maps, indicating the tsunami inundation zone and the safest place where to evacuate, and public outreach activities informing different target categories of people/organizations of risks and protective actions. Examples of public education as a mitigation measure are the attempts to create a new disaster subculture (Velotti et al. 2013) and educating people to self-assess the danger and take action. The creation of a new disaster

subculture in the case of tsunami relies on the Japanese concept of Tendenko, meaning "each for themselves" (Yamori 2014). Tendenko teaches people mutual trust in the fact that everybody will attempt to gain safety; this approach saved many lives during the 2011 Tohoku earthquake/tsunami. Education proved to be meaningful in saving the lives of Japanese school children at Unosumai, Kamaishi City, where the children were able to self-assess the safest location on the basis of the wave height and evacuated uphill rather than to the third floor of their school (Fraser et al. 2012; Harding and Harding 2011; Hein 2014; Yamori 2014).

Natural resources protection in case of tsunamis is aimed at preserving the natural landscape as a way to slow the tsunami forces. For instance, in the aftermath of the 2004 Indian Ocean tsunami, there has been greater advocacy for the restoration of mangroves along the beaches as a mitigation measure.

Structural projects involve the use of engineered structures such as seawalls, dams, vertical structures, and so on. The protective ability of structural projects is limited by the provision of safety up to a preplanned threshold (Berke and Campanella 2006; Burby et al. 2000; Burby 2006; Burby and Dalton 1994; Clary 1985; Highfield and Brody 2006; Mileti 1999; Rossi et al. 1982). For instance, a dam or a seawall can be designed to withstand a predetermined impact, but once that threshold is passed, the structural integrity of the dam or seawall can no longer be guaranteed. Thus, structural projects could result in the "safe development paradox" (Burby 2006). For instance, the government's authorization to develop an area that is at risk could have an unintended consequence in the event of structural protection failure. For example, people might feel safe that they are being protected by a dam and do not undertake any other mitigation measure.

Tsunami Protective Actions

Vertical evacuation (VE) has been adopted, implemented, and tested as a protective strategy in Japan to handle tsunami and in Bangladesh to handle recurrent hazards such as cyclones (Nirupama 2013). Attempts to implement VE are also being made in some of the countries affected by the December 26, 2004, Indian Ocean tsunami (GeoHazards International 2014). Examples of vertical shelters built for VE are the Nishiki tower and the Tasukaru (life-saving) tower. The Nishiki tower is a multi-purpose building used as the mayor's office and a tsunami museum to promote awareness. It has a capacity to hold approximately 500 people, has a height of 71.5 feet, and has a sheltering area starting at an elevation of 66.2 feet (Nakaseko et al. 2008). In addition to the Nishiki tower, 16 other shelters were built between 1994 and 2005. The Nishiki tower also serves the mitigation goal of educating and making people aware of the tsunami threat.

These buildings are the starting point for discussions on the adoption of vertical shelters or tsunami VE building (Fraser et al. 2012) and VE in the United States in the States of Washington and Oregon. Nowadays, the first vertical evacuation shelter in the United States has been built at the Ocosta School in the State of Washington.

Conclusion

In conclusion, a tsunami triggered by earthquake is a complex hazard to be planned for because of the many variables and uncertainties involved. In the mitigation stage, the best measure could be not allowing people to live in at-risk areas; however, this is not always the best solution since people are resistant to resettlement and moving communities is expensive. Vertical evacuation shelters seem to be a viable solution to help those who will not be able to reach high ground on time and eventually also the most vulnerable population such as the elderly and the people with impairment, for instance. Resistance toward the building of vertical shelters in the United States is due to the fact that these shelters are not safe but are the safer option in some specific cases. Government representatives are afraid of being liable for loss of lives in case the shelter is overtopped by a tsunami wave.

Natural Hazards: Volcanic Eruptions

Hung-Lung Wei
Department of Security, Fire, and Emergency Management, John Jay College of Criminal Justice, CUNY, New York, NY, USA

Keywords
Ash · Earthquakes · Evacuation · Lava · Magma · Silicosis · Tephra

Definition

Volcanic eruptions refer to the types of activity, such as discharge of steam and other gases, lava, and gas-laden debris, which lead to a variety of associated problems (e.g., landslides, fires, property destruction).

Introduction

There are different types of volcanoes in terms of size and morphology. Siebert et al. (2015) indicated that "Volcanic landforms vary widely in size and morphology from the stereotypical towering glacier-clad stratovolcano. They range from small spatter cones to massive shield volcanoes several thousand cubic kilometers in volume or broad volcanic depressions, cinder cones being the most common volcanic construct. Their eruptions likewise span many orders of magnitude in volume" (p. 239).

Volcanic activity (e.g., explosive eruptions, pyroclastic flows, lava flows, lahars, ash fall, gases, acid rain, etc.) can cause a number of casualties and economic losses worldwide. For instance, Witham (2005) discovered that 491 volcanic eruptions in the twentieth century produced massive impacts on mortality, morbidity, homelessness, economic collapse, and destruction of both the human-built and natural environments. In order to protect people's lives and their property from damage, it is important to understand scientific research on volcanic eruptions, mitigation strategies, and preparedness strategies for volcanic eruptions.

Research on Volcanic Eruptions

The importance of volcano research is underscored by many international scholars who have examined volcanic risk perception or the extent of hazard adjustment adoption or both (Barberi et al. 2008; Carlino et al. 2008; Finnis et al. 2010; Gaillard 2008; Gavilanes-Ruiz et al. 2009; Haynes et al. 2008; Jóhannesdóttir and Gísladóttir 2010; Paton et al. 2008; Perry and Lindell 2008; Sagala et al. 2009; Wei and Lindell 2017). In addition, other researchers have studied volcanic risk communication (Barberi et al. 2008; Bird et al. 2009; Carlino et al. 2008; Haynes et al. 2008; Wei and Lindell 2017) and evacuation (Barberi et al. 2008; Bird et al. 2009; Carlino et al. 2008; Chenet et al. 2014; Jóhannesdóttir and Gísladóttir 2010; Marrero et al. 2013; Mei et al. 2013; Wei and Lindell 2017; Woo 2008).

In a recent volcano study of Mt. Rainier (which has not erupted since 1894), Wei and Lindell (2017) reported the average risk perception of respondents was relatively low ($M = 2.4$, based on a 5 point scale). Peacock et al. (2005) suggested that increasing public participation and people's psychological reactions to their hazard exposure are significant factors that can influence the content of hazard mitigation programs and, thus, allow people to prepare for and respond to environmental hazards. In addition, people's risk perceptions are likely to have an effect on community hazard adjustments such as emergency preparedness programs, building codes, and land use planning policies. Therefore, local and state governmental officials need to devise strategies that can improve the accuracy of people's risk perceptions in order to allow them to prepare for and respond to disaster threats appropriately. Wei and Lindell (2017) mentioned that risk communication strategies should address message content by describing the personal consequences of hazard impact and should provide repeated messages in order to increase the frequency of thought and discussion about the

hazard. Risk communication programs that are designed in this way to produce affective reactions and appropriate hazard adjustments commiserated with risk level. Moreover, Wei and Lindell (2017) concluded that most respondents had low levels of hazard intrusiveness (i.e., blending of information due to people thinking and discussing hazard-relevant information with family members or peers), resulting in very few of them to engage in volcano-specific emergency preparedness actions; consequently, local emergency managers must find effective ways to increase residents' volcano hazard awareness and preparedness to reduce potential harm from residents' poor planning in response to volcano eruptions.

Mitigation and Preparedness Strategies for Volcanic Eruptions

Lindell et al. (2006) described four mitigation measures (i.e., community protection works, land use practices, building construction practices, and building contents protection) that are suitable for volcanic eruptions. Andreastuti et al. (2018) noted that an effective disaster mitigation plan should incorporate culture and local resources and implement it through a best mitigation education program. This education program must provide the early warning system and evacuation model for the area where the community is located, allowing the community members to understand how to take protective actions such as evacuation. Also, Andreastuti et al. (2018) emphasized that effective community's responses to volcanic eruption rely on close coordination and collaboration between government and community.

Risk communication strategies can protect people's lives from volcanic eruptions. Stone et al. (2014) discussed a network of volunteers known as vigías (a community-based volcano monitoring) and discovered the vigías network functions simultaneously as: (a) a source of observational data for scientists; (b) a communication channel for increasing community awareness, understanding of hazard processes, and enhancing preparedness; and (c) an early warning system for civil protection. In a recent study of risk communication films, Hicks et al. (2017) demonstrated that risk communication is most effective when approaches are integrated into risk reduction strategies and/or research projects from the outset, and the audiences are identified, their needs are known, and they are motivated to participate in the risk communication process itself. Furthermore, communicating risk across hazard contexts and settings can support the management and reduction of risk and strengthen resilience of communities to disasters (Hicks et al. 2017).

Conducting vulnerability assessment is an important strategy for volcanic eruptions because it helps local officials and emergency managers understand and communicate where potential loss of life may be concentrated and where to focus on risk reduction efforts (Diefenbach et al. 2015). Local government agencies can apply Geographic Information System (GIS) tools to map risk areas and locations of critical infrastructure (e.g., telecommunication networks, natural gas networks, electric grids, key transportation routes, schools, hospitals, etc.) and determine values of buildings and residents that will be affected by volcanic hazards.

In a study of ash fall preparedness, Wilson et al. (2014) described a collaborative process used to create a suite of ten posters designed to improve the resilience of critical infrastructure organizations to volcanic ash fall hazards. This collaborative process attempted to create a partnership between critical infrastructure managers, other relevant government agencies along with volcanic impact scientists, and eventually translate volcanic impact research into practical management tools.

Conclusion

In the United States, local and state Departments of Emergency Management should collaborate with the USGS Volcano Hazards Program to disseminate volcanic risk maps to residents and conduct social vulnerability analysis to identify the vulnerable populations with regard to the volcanic threats (e.g., pyroclastic flows, lava flows, lahars, ash fall, gases, acid rain, etc.). It is important to increase the awareness of community

preparedness, and it can be achieved in several ways. For example, educating the children in public schools (K-12) could be efficient and beneficial because it allows them to discuss the early warning system and evacuation plan with their parents. Community organizations can be trained to play an important role in instructing people about the early warning system and evacuation plan. Finally, local emergency managers should arrange meetings for explaining the evacuation plan and provide incentives for promoting public participation.

Personnel Security: Hiring

Thomas Shea
Police Graduate Studies Program, College of Education and Human Services, South Orange, NJ, USA

Keywords
Private security · Physical security · Background investigations

Definition

Since the unfortunate events of September 11, 2001, there exists a newfound and prevalent dependency on private security in the United States. Government officials do not protect the majority of private infrastructure in this country, but rather, private security officers. An effective private security position is one that requires trust and integrity, as well as a sense of professionalism. The hiring of incompetent personnel can result in litigation, loss of revenue, and personal harm to both employees and clients in organizations. There are multiple layers of security-oriented vetting, but the preemployment hiring process is crucial to meeting objectives while safeguarding organizational assets. The likelihood of the unsuccessful hiring of an employee is usually correlational to the extent of background investigations conducted before employment.

Introduction

"Personnel security," as defined by Ortmeier and Johnson (2017), "involves protection of people associated with the organization as well as protection from those who might harm the organization or its people (p. 98)." Individuals selected for employment as personnel security officers are often granted access to sensitive information and secure physical facilities not normally accessible to the public. Unlike policing, where the objectives are to detect and apprehend criminals, the goal of security personnel is more to deter and prevent criminal activity in the first place (Blackstone and Hakim 2010). Also, there are many functions that do not require the advanced training or authority of sworn police officers. The expectation by employers and managers is that security personnel will be trustworthy and loyal to their respective organizations (Center for Development of Security Excellence-Personnel Security 2017).

According to the Bureau of Labor Statistics and as of May 2018, there were 1,114,380 security guards employed in the United States, the majority geographically located in the Northeastern United States (Bureau of Labor Statistics 2018). The majority of those individuals' work in general investigative and security job descriptions, though other descriptions included schools, hospitals, banks, and establishments that serve alcohol. There is a greater reliance on private security in many nations with respect to crime prevention and

L. R. Shapiro, M.-H. Maras (eds.), *Encyclopedia of Security and Emergency Management*,
https://doi.org/10.1007/978-3-319-70488-3

detection, than solely having policing strategies in place (Johnston and Shearing 2003; Stenning 2000). In fact, it is estimated that there are twice as many private security personnel than police officers (UN News 2011). There are multiple needs and uses for private security, ranging across many infrastructural and occupational functions. The American Society of Industrial Security or ASIS (https://www.asisonline.org/), one of the world's largest and one of the most reputable security organizations in the world, listed 18 security functions, including, but not limited to:

> . . .physical security, personnel security, information systems security, investigations, loss prevention, risk management, legal aspects, emergency/continuity planning, fire protection, crisis management, disaster management, counterterrorism, competitive intelligence, executive protection, workplace violence, general crime prevention, Crime Prevention Through Environmental Design (CPTED), and security architecture. (2001)

Trends indicate that private security is the primary means of protection in the United States (Cunningham and Strauchs 1992) and worldwide (Bayley and Shearing 2001). Secondly, the profession consistently grows every year (Bureau of Labor Statistics (BLS) 2010; Behar 1992). Many commercial airports in the United States employ private security instead of TSA agents (Nixon 2016). With this many individuals employed in the myriad locations described, the chances for citizens to engage in contact of some form with security guards are high (Cunningham and Strauchs 1992). Professionalism displayed by security personnel during these interactions is of the utmost importance to create legitimacy for the organization.

According to a study by Nalla and Crichlow (2017), there is no standard protocol for the training of newly hired guards and some do not even require minimum educational standards or criminal background checks. Guards themselves also admit that the lack of training received hinder the ability to perform their jobs effectively (Cobbina et al. 2013). The creation of an accredited program for security guards has the propensity to improve the overall standards of the profession (Adolf 2011) but, so far, that has not occurred. This oversight has an inclination to increase liability for the respective, aforementioned organizations, and affect the morale of personnel security staff.

With the existing lack of consistent and reputable hiring standards, the possibilities of incidences occurring that can create liabilities increases as well. Hiring qualified security personnel is the most critical aspect of building a respected and effective security paradigm (McAdams 2004). Secondly, the complete legitimacy of the private security occupation is linked to the level of professionalism shown by employees (Nalla and Hwang 2006). Selection of the most qualified individuals available is integral to accomplish those lofty goals.

The First Step: The Background Check

A thorough, comprehensive background screening investigation must be performed on all applicants to avoid hiring an individual not qualified or who might have a criminal background. Prospective employees should be comprehensively checked to avoid missing troubling determinants in their pasts. The detection of past infractions does not usually prove to be difficult (Power and Forte 2006); however, without a unified database that screeners can utilize to retrieve background information, an incomplete investigation may be the result (Brody 2010). This concern is legitimate; however, it can be mitigated with a proficient investigator. Past reforms in personnel security clearance improved the speed and efficiency of investigations, yet those improvements remain debated by professionals and experts (Miles 2012). At a minimum, inclusion and examination of the following records should be a part of a background investigation (Fay 2011; Russell and Arlow 2015):

- State, local, national police
- Former employees
- Public records
- Credit agencies
- Schools at all levels
- References *not* furnished by applicants

Other preemployment techniques are also effective, such as "honesty," or "integrity" tests. During both tests are asked questions based on scenarios where applicants have to make ethical decisions. An example of this might include the decision whether to report a fellow employee that the applicant witnessed committing theft. Certain companies do not like to utilize these tests because some employees consider such questions offensive and an invasion of privacy (Sackett and Harris 1984). Yet, a home improvement store chain initiated an integrity test as part of their hiring process that resulted in a 50% reduction of employee terminations for theft, drug use, and violence (5 year period) (Brown et al. 1987). Terminations of employees due to misconduct create unnecessary turnover, time, and cost for the organization. Terminations for these reasons can be averted by conducting strict due diligence (Gregory 2015), therefore it should be a priority during an initial hiring process.

According to Sissons (2002), there are pragmatic vetting techniques that organizations can adopt to achieve thorough and comprehensive preemployment screening, including: (a) an explanation of the particular position so that they understand that it is more involved than infrastructure protection and also requires discretion, (b) ensuring that the applicant has verified first aid training, (c) the use of fair and adequate assessment tools, and (d) if employing applicants from an outside vendor, check the references of that company and not just the applicant. Many companies choose to employ contract security over in-house personnel because of the flexibility and cost benefits (Button and George 2005). Whether choosing to employ outsourced security personnel or not, the company is obliged to assure training and needs requirements are met (Papi 1994; Rosenberg 2007). Some organizations choose to train contracted staff in house, while others delegate that responsibility to the security vendor. With either choice, however, the hiring organizations are still liable for the acts of security personnel.

Sennewald (2011) outlines more intrinsic values that an organization should examine in security personnel candidates, such as: (a) the need to be free from mental or physical disorders that would affect performance standards; (b) demonstration of maturity, integrity, and responsibility; and (c) the absence of criminal convictions involving "moral turpitude" (p. 61). However, the promulgation of a screening process that evaluates ethical and moral values may be difficult due to its subjective nature. The combination of empirical measurement tools coupled with personnel trait assessments may develop a more complete screening instrument for employers. Even so, the evaluator must also be trained in human resources techniques to ensure correct vetting procedure implementation.

Upon hiring, employers should advise applicants that they will be monitored during the course of their daily duties. Applicants should also be notified that they must accept all mandated conditions upon acceptance of the position (Mitrou and Karyda 2006). Examples of these conditions include drug testing, credit checks, and social media checks, among others. Furthermore, employers have the incumbent responsibility to confirm that all prospective staff understand and are trained to adhere with the policies and regulations of the organization (Lincke 2015). Should a future incident occur that causes a potential litigious situation, there is a tendency for attorneys from both sides to seek this information as evidence to prove their case. There is no quicker practice to lose civil lawsuits than maintaining failure to train liabilities within an organization. Prudent safeguarding regarding personnel practices is recommended to reducing this exposure (Meadows 1987).

Negligent Hiring

There are consequences for not performing competent due diligence on personal security before officially hiring them. Because of the historical lack of statutory training requirements required in many states (Moore 1988), there remain openings for potential litigation. Indeed, an increase in negligent liability exposure has occurred in the forms of claims (Blackstone and Hakim 2010). Deficiencies in personnel hiring procedures only raise the chances of hiring a substandard

employee and increase risks of negligent hiring allegations (McCrie 2015). Courts do not take kindly to organizations' lack of accountability for not vetting their security applicants. There have been repeated rulings deeming that it is the responsibility of organizations to know whom they are hiring and if they are fit to carry out the proscribed duties for which they are responsible (Service 1988). Further, the employer is responsible for the acts committed by the employee under the legal doctrine "respondent superior" (Kaplan et al. 2012), which is a vicarious liability concept. Knowledge of the negligence or participation by the defendant is not even a necessary requirement to file a claim, illustrating the comprehensive dangers for employers. Through numerous rulings, the courts have outlined precisely how employers expose or raise risks of negligent hiring inside their organizations. Human resources personnel assigned the task of vetting personnel security should familiarize themselves with these delineated preventative measures. In basic terms, three requirements must exist to establish civil liability: (a) a legal duty by the plaintiff to protect the defendant, (b) a failure by the plaintiff to do so, and (c) damage or harm to the defendant as a result of that failure (McCrie 2015). Not conducting a thorough, competent background investigation that results in that subsequent harm certainly exposes companies to needless risk.

Conclusion

There exists the negative characterization that most private security professionals are uneducated and poorly paid (Kakalik and Wildhorn 1972). While this stereotype is not accurate, as most take their duties and responsibilities seriously (Lipman 1988), state regulation of private security is fragmented and loosely based (Bilek et al. 1981). There are precautions that organizations must take to protect themselves, which starts in the hiring process. The most critical influencer to creation of a competent and effective security culture is directly dependent on a belief of security importance by all parties involved (Connolly 2000). This point is especially true regarding organizations' employees and most importantly, its security employees. In the business realm, the importance of security is imperative to survival (Chia and Ruighaver 2002). When returns on investments result from smart security decision-making, that money can be used for other security and organizational projects (Vellani 2006).

Proper security staffing can be a time consuming, costly venture. There is likely aversion to these processes on the part of many organizational executives. Falling into that trap and taking the easy ways out may very well lead to more costs and wasted time later. A careful executive should realize that these vulnerabilities are not worth saving a few dollars at the inception. The hiring of top-quality professionals should be a top concern for stakeholders. Doing so will reflect well on the organization, reduce liability concerns, and increase cooperation and collaboration with local law enforcement. Failing to do so could result in detrimental effects for organization and their respective stakeholders.

Recruitment · Hiring · Personnel security · Internal hires · Referrals · Intellectual property theft · Data security

Definition

Personnel security recruitment refers to activities that influence the number and types of applicants who apply for a security-related position, remain in the applicant pool, and accept an employment offer (Breaugh 2008).

Introduction

Traditionally, companies have relied on IT departments and firewalls to protect information, and employees have been viewed as the weakest link. Increasingly, however, companies are relying on employees to be the first line of defense, and thus human resources processes and policies are becoming imperative to protecting organizations from risks and violations of security. There are three major ways that employees can engage in security breaches in organizations. First, employees can be manipulated by outside influences such as hackers or phishing schemes. For example, in 2015, the US finance team at Ubiquiti made a multimillion dollar transfer for a senior executive, only to later find out that a criminal was posing as the executive (Sollars 2016). Second, employee negligence or error can lead to security breaches. In fact, 27% of all data breaches are caused by human error, versus 48% of breaches being caused by hackers or criminal insiders (IBM Security and Ponemon Institute 2018). Finally, the misuse of access to information, including theft, is another way employees can engage in security breaches.

Since it is frequently incumbents engaging in these violations, organizations can minimize the risk of such security violations by ensuring that individuals who are hired do not pose a security risk. While this is generally accomplished through utilizing appropriate screening methods during selection decisions, targeting individuals with the desired characteristics and treating them with consideration during the recruitment process can be an important first step. Accordingly, in this chapter, two methods of maximizing personnel security will be explored: (a) utilizing appropriate recruitment methods to target the desired candidates and (b) ensuring that applicants develop positive reactions to the organization.

Employee Recruitment

Employee recruitment refers to practices aimed at generating a qualified applicant pool, through strategic human resource planning (Mathis et al. 2017). In addition to attracting high-quality applicants who would likely perform well on the job, another organizational recruitment objective which specifically relates to personnel and people security involves attracting individuals who would not pose a threat to the organization's physical and intellectual assets. Depending on the type of position and/or organization, such as public or civil service, risks of violation may be deemed more or less severe and may necessitate greater consideration. Employee selection begins with the recruiting process. Accordingly, tailoring recruitment methods to attract applicants with the desired qualities, such as trustworthiness and reliability, may help organizations reach their security goals and thus have greater implications on the condition of the organization as a whole.

Goals of Employee Recruitment

Recruitment is the first essential element of talent acquisition. The overall objective of recruitment is to capture the attention of desired applicants and subsequently motivate these individuals to apply (Acikgoz 2019). Accordingly, the first step in the recruitment process is determining what the expected set of qualities are for an ideal applicant. This includes identifying the necessary knowledge, skills, abilities, and other characteristics, or KSAOs, by conducting a job analysis (Mathis et al. 2017). Employee trustworthiness and integrity are important aspects of applicant quality and job performance in any public or private organization, especially with regard to personnel security for companies with large intellectual repositories or physical assets. Organizations entrust their assets with the individuals they employ, and this requires a high level of trust between the individual and the

organization. In addition, organizations may wish to use the recruitment process to maximize applicant quality, diversity, job performance, job satisfaction, and employee retention while reducing the cost of hiring.

Once organizations have determined the key characteristics that are necessary for success on the job for vacant positions, the organization can gain a better picture of how to reach out to individuals with those attributes. In terms of ensuring personnel security, organizations can target individuals within certain characteristics who are likely to pose minimal risk. Strategic and targeted recruitment can aid in attracting individuals who can be entrusted with the physical and intellectual assets of an organization (Breaugh 2008). Various methods of recruitment, including internal job postings, employee referrals, and a focus on recruiter trustworthiness, are likely to be effective in accessing certain demographics, which will be explored in more depth in the next section.

Employee Recruitment Methods

According to Breaugh (2008), employee recruitment methods refer to any measures taken on behalf of an employer to provide potential applicants with an awareness of job openings. After determining recruitment objectives, recruiters can begin to design a strategy based on whom to recruit, where to recruit, what sources to use, and what message to communicate (Breaugh 2008). One distinction to be made in recruiting is between formal and informal methods, which are also referred to as direct and indirect methods. Formal methods are conventional routes taken by organizations to make professional contact with potential applicants, which include media advertisements, point of purchase methods, direct mail, employment agencies, college recruiters, computer databases, online job ads, and company websites. On the other hand, informal methods typically involve an applicant taking the initiative to contact an organization or a current member of the organization, organizations hiring from within by reaching out to their current or former employees, or a current employee referring a potential applicant for a job opening. Accordingly, informal methods include direct applications, employee referrals, and internal job postings.

A large body of research (Breaugh and Starke 2000; Castilla 2005; Zottoli and Wanous 2000) supports the advantages of informal methods, especially employee referrals and internal job postings. For example, employee-referred applicants are likely to have better job performance during the first 2 months of employment compared to those hired through formal methods. One reason for this phenomenon is that these employees have access to "difficult to obtain" information and face pressures from employees referring them to perform well (Castilla 2005). Internal hires can help to fill vacant positions in less time and thus with lower opportunity costs and financial costs than do external postings. Internal hires can also boost employee morale through the exemplification of workplace mobility. In addition, internal hires are more likely to be familiar with and aware of the corporate culture than external hires (Mathis et al. 2017). It is of little surprise that these methods lead to good post-hire outcomes, such as higher job performance and longer tenure than external hires (DeOrtentiis et al. 2018; Zottoli and Wanous 2000). The superiority stems from the fact that internal hires, especially employee referrals, are already vetted by the organization for competency and cultural fit before even entering the applicant pool, or in the case of hiring from within, the candidates are already well-known by the organization (Mathis et al. 2017).

In addition, internal promotion has been linked to higher levels of organizational commitment (Pinks 1992). Research (Dalal 2005; McClurg and Butler 2006) demonstrates a negative relationship between organizational commitment and counterproductive work behaviors. Counterproductive work behaviors are defined as intentional employee behaviors that are harmful to an organization's' interests and include areas of behavior such as theft and fraud (Dalal 2005). McClurg and Butler (2006) even proposed a conceptual model linking organizational commitment specifically to lowered instances of workplace theft. Accordingly, internal recruiting methods have

many positive outcomes for reducing security risks within an organization. Internal hires are indoctrinated to the organizational culture, and internal promotions increase organizational commitment. Internal hires generally have demonstrated performance capabilities and trustworthiness. Internal recruiting is thus an exceptional method for mitigating counterproductive or deviant work behaviors, such as theft, and reducing security risks within an organization.

Applicant Reactions

Applicant reactions refer to the attitudes, thoughts, or opinions formed by applicants regarding the organization during the recruitment and selection process (Ryan and Ployhart 2000). The reactions of the applicants can influence the decision to remain within the pool and potentially accept an offer (Turban and Cable 2003). Applicant reactions are influenced by personal characteristics, such as work experience, personality, and demographics but are also highly influenced by perceived procedure characteristics, job characteristics, and organizational context (Hausknecht et al. 2004). Organizations can foster positive reactions through recruitment procedures by considering the length and outcomes of the recruitment process and ensuring a fair treatment of the applicants during recruitment and selection. Positive reactions to the recruitment process (procedural justice perceptions) have a positive relationship with favorable organizational outcomes and organizational citizenship behaviors (Hausknecht et al. 2004). Organizational citizenship behaviors, or behaviors that an employee engages in that are unrewarded but nonetheless benefit an organization's performance, are negatively related to deviant work behaviors, such as theft or fraud (Dalal 2005). In addition, applicants with positive reactions to the recruitment process are less likely to leave the organization once hired. Garnering positive reactions from applicants will likely result in the retention of trustworthy and high-performance employees, in which the organization can invest time and money. Accordingly, by making sure that applicants have positive reactions during the recruitment and selection procedures, organizations can improve personnel security outcomes.

There are many ways organizations can improve applicant reactions during recruitment and selection. An applicant's perception of procedural characteristics influences overall judgments of fairness and general attitudes toward tests and selection. One facet of perceived procedural characteristics is job relatedness, which is composed of face validity and perceived predictive validity (Hausknecht et al. 2004). Face validity refers to the extent to which selection procedure content appears on the surface to be related to job content, whereas perceived predictive validity refers to the extent which selection procedure content seems to predict future job performance regardless of appearance. Face validity and perceived predictive validity are strong predictors of many applicant reactions, including procedural justice, referring to the fairness perceptions regarding the process through which selection decisions are made, and distributive justice, which refers to the perceived fairness of these decisions. These perceptions of justice have been found to predict several important outcomes, such as organizational attraction and intentions to litigate against an organization (Ababneh et al. 2014). In addition, applicants who hold positive perceptions about testing and selection in general are apt to view favorably those organizations using such tools.

Perceived procedural characteristics are positively related to applicants' perception of selection procedure fairness, which are related to overall attitudinal and behavioral outcomes (Hausknecht et al. 2004.) For example, research by Breaugh and Starke (2000) found that recruiters who appeared to be low on expertise and trustworthiness caused applicants to withdraw from the pool. In fact, it was found that individuals who viewed a recruiter as personable and trustworthy were more attracted to a position with the organization than those who perceived the recruiter to be low in those qualities (Chapman et al. 2005). If organizations are able to convey a culture of fairness and trustworthiness, applicants will be likely to reciprocate this virtue. In addition, researchers examining trustworthiness as a predictor of justice perceptions (Zapata et al. 2013) and on employee misconduct have found

that low perceptions of justice are a leading indicator of workplace theft (Jex and Britt 2008). This correlation may occur because employees frustrated with organizational procedures attempt to take control the situation by engaging in deviant behaviors.

Measuring Effectiveness

Metrics of recruitment effectiveness can be divided into two domains – the objectives that are fulfilled either pre- or post-hire. Pre-hire measures include the number of applicants, quality of applicants, and the reactions generated. Some post-hire measures are cost and time to fill positions, first-year hire retention rates, job performance, and diversity impact. Evaluation results should demonstrate the value of the recruitment methods used in regard to attainment of organizational goals and should be used to further improve the recruitment process within the organization by increasing cost/time efficiency. Organizations with high risk of data violations or personnel security risks may also evaluate their recruitment efforts in terms of organizational outcomes that pertain to the mitigation of those risks. For example, organizations can examine whether employees coming from a specific recruitment source tend to be more or less likely to engage in security violations and compare results across various methods. Metrics on recruitment methods can be used in comparison to various organizational outcomes to rate the effectiveness of specific methods and increase the likelihood of attracting talent that meets organizational goals.

Conclusion

Recruitment is the first step in acquiring quality employees and ensuring the prosperity of an organization. A wide variety of methods are available, making it important that an employer identifies the value and desired outcomes of filling any vacancy before deciding how to implement the process. Some positions are of higher importance than others, which often equates to a need to have strict safety requirements. However, personnel security violations exist as a potential risk for many position levels in a corporate environment. Though there is no way to completely eradicate personnel security risks, taking applicant reliability into consideration during the recruitment process can significantly reduce the likelihood of violations.

Personnel Security: Retention

M. M. Laske, Maira Compagnone and Yalcin Acikgoz
Department of Psychology, Appalachian State University, Boone, NC, USA

Keywords
Retention · Personnel security · Turnover · Job satisfaction · Talent management

Definition

Personnel security	Policies and procedures aimed at mitigating the risk of employees exploiting their access to an organization's resources for purposes outside of their employment purview
People security	Relates to the organizational environment and security culture
Retention	"Actions to keep employees motivated and focused so they elect to remain employed and fully productive for the benefit of the organization" (SHRM 2019)
Attrition	"The overall reduction in the workforce, including vacancies that go unfilled and jobs that are eliminated" (Sonsino 2017)

Commitment	"The sense of dedication that employees feel toward the companies and organizations they work for" (Kivak 2019)
Organizational citizenship behavior	"Individual behavior that is discretionary, not directly or explicitly recognized by the formal reward system, and that in the aggregate promotes the effective functioning of the organization" (Organ 1988, p. 4)
Counterproductive work behavior	"Behavior that explicitly runs counter to the goals of the organization" (Jex and Britt 2008, p. 168)
Job satisfaction	"The extent to which people like (satisfaction) or dislike (dissatisfaction) their jobs" (Spector 1997, p. 2)

Introduction

Retaining employees and reducing employee turnover is of importance for the promotion of personnel security. In 2018, there were 40.1 million separations in which employees voluntarily initiated the change, while there were 21.9 million layoffs or discharges for the same time span (U.S. Bureau of Labor Statistics [BLS] 2019b, March). These data indicate that employees are leaving positions at a greater rate than they are being laid off or discharged. It should also be noted that the job opportunities have been increasing since July of 2009 and reached a peak of 7.3 million openings in December of 2018 (BLS 2019a, February). This could indicate that organizations not only have to be concerned about turnover costs, which are estimated at $567 billion annually (Working Institute 2018), but also about retaining high-quality personnel.

In addition to the financial burden of losing qualified employees as a result of voluntary turnover, retention is also important because with every replacement comes a new employee who is not yet as well-known and trusted as the employee who is replaced. This may bring some personnel security threats, which may include such actions as theft, workplace sabotage, and misuse of company resources, which can be quite costly. In fact, 6% of employees reported knowledge of fraudulent, illegal, or unethical activities in 2017, an increase from 1% in 2010 (Work Institute 2018). These data indicate a growing concern regarding personnel security among organizations. Although these reports do not specify the number of these occurrences, data are available on the costs of such misuses of company resources. For example, the average total cost of a data breach in the United States is estimated to be close to $8 million, while the average cost of a single lost/stolen record is $233 for the United States (Ponemon Institute 2018). Because of these substantial costs, reducing employee turnover and increasing retention of loyal and highly competent employees are of importance. Strategies to promote retention and therefore reduce potential issues of personnel security include increasing organizational commitment, focusing on talent management, and increasing job satisfaction. These areas of focus can help organizations retain top, trusted talent and thus reduce security concerns related to personnel.

Turnover

An important distinction in terms of employee retention can be made between optimal and dysfunctional turnover. Not all turnover is created equal, as there are times when it may make financial sense to have someone leave an organization. Optimal turnover occurs when poor performing or untrustworthy employees voluntarily leave an organization, whereas dysfunctional turnover refers to high performing employees, the talent that organizations want to keep, leaving an organization. Dysfunctional turnover is the type of turnover that needs to be addressed through the development of retention strategies. These employees may react to financial incentives, but often the decision to leave a company is made because of other concerns, such as the

organizational culture, opportunities for promotion and development, supervisors, location, or even familial concerns. Organizations can minimize the impact of some of these extraneous variables by focusing on effective talent management strategies and tactics to increase job satisfaction. These strategies will increase organizational commitment, loyalty, and thus retention within the organization.

Antecedents of Retention

Organizations, through the attention they provide their employees with, can develop emotional bonds between the organization and the employee, known as social bonds (McClurg and Butler 2006). These affective components, or feelings of attachment to an organization, are part of organizational commitment (Mathieu and Zajac 1990). Organizational commitment was shown to be negatively related with intentions to search for other employment opportunities and intentions to leave an organization (Mathieu and Zajac 1990), especially when employees have high perceptions of employability (Acikgoz et al. 2016). In addition, research consistently shows that employees with more ties to an organization, whether those ties are demonstrated through (a) their tenure, (b) their lack of turnover intention, or (c) their organizational commitment, are less likely to steal (McClurg and Butler 2006). Work engagement, or employee engagement, takes organizational commitment a step further, and states that as a result of the emotional bond with the organization, employees are more likely to engage in acts that further the organizational goals, through vigor, dedication, and absorption (Schaufeli et al. 2002). Work engagement is related to a number of beneficial organizational outcomes, including improved job performance, increased effort, innovation, and higher numbers of organizational citizenship behaviors (Pandita and Ray 2018).

Three top drivers of work engagement include (a) the opportunity to use skill sets, (b) alignment between employee and employer values, and (c) the belief that the employee's efforts will make a difference in the organization (Johnson and Pike 2018). These drivers can be greatly impacted by two important antecedents of work engagement: effective talent management strategies and job satisfaction.

Talent Management

Talent management is a very broad term that covers many general human resource duties that are mainly concerned with attracting and keeping top talent within an organization, which includes methods that increase employee engagement. One of the most impactful ways that organizations can retain top talent and combat dysfunctional turnover is through workforce development. In fact, the Work Institute's 2018 Retention Report found that the top reason employees left their jobs was related to a lack of development opportunities (21%), along with work-life balance concerns (13%), and manager behavior (11%). Thus, a focus on career planning, development, and training can significantly reduce employees' desire to turn to another company for those opportunities. Successful employee development programs should include a diverse mix of some of the following strategies: coaching, mentoring, individual development plans, talent assessments, "stretch" assignments, job enrichment, job shadowing, job rotation, and succession planning. These strategies allow employees to explore different roles within the organization, test out new ideas, and develop skills that will allow for positive career growth. Some organizations are under the mistaken impression that developing employees will lead to attrition, as employees receive skills that are highly transferable in the external labor market. However, research has shown that skill utilization obtained from development opportunities leads to a decrease in employee turnover intentions (Nelissen et al. 2017). This is a considerable finding as employee intentions to quit are strong predictors of actual turnover (Griffeth et al. 2000). Organizations can also increase the retention of top performers by matching skill set improvements with an increase in compensation, commensurate to the

employee's external value in the relevant labor market (Anis et al. 2011). By focusing on developing top talent and increasing employee engagement, organizations can reduce turnover and retain employees who are proven performers with organizational loyalty, which in turn means retaining the employees who are known and trusted. These employees will be less of a risk for potential concerns surrounding personnel security.

Job Satisfaction

Job satisfaction is defined as "the extent to which people like (satisfaction) or dislike (dissatisfaction) their jobs" (Spector 1997, p. 2). It may seem like common sense to insinuate that a happy worker is a good worker, but the relationship between job satisfaction and superior workplace outcomes is more complicated. More than the reduction to "happy," or "satisfied," job satisfaction is comprised of affective, cognitive, and behavioral components (Judge et al. 2001). Affective satisfaction represents the employee's feelings toward their work and their employer, while cognitive satisfaction is represented by the employee's beliefs about their job and employer (such as believing that a job is boring or stimulating). Affective and cognitive evaluations about the quality of work are often dependent on one another. The belief that a job is too menial or repetitive, for example, may lead an employee to have a negative affect or disposition toward the work. Behavioral tendencies, represented within the behavioral component of satisfaction, such as regular attendance to work or high job performance, may reveal job satisfaction in a different way. The interaction of these three components is often why the cliché statement "a happy worker is a hard worker" is so often espoused. Employees who have positive beliefs about their employer and their job will generally have more positive affect toward their job, which will lead to better citizenship behaviors within the workplace.

Due to the high financial costs of turnover and potential of misuses of company information upon termination, it is important to increase employee job satisfaction, as it is related with lower instances of turnover (Carsten and Spector 1987; Valentine et al. 2011). Employees high in job satisfaction are also more likely to engage in the culture-building behaviors that will promote the values and culture that an organization wishes to foster. Dalal (2005) found that job satisfaction was related to lower instances of counterproductive work behaviors. These findings support the idea that higher job satisfaction will lead to organizational commitment and lower rates of turnover.

A number of organizational initiatives can increase job satisfaction among employees. Specifically, job satisfaction is influenced by (a) perceptions of fairness in terms of organizational procedures, (b) levels of respect and trust between employees and senior management, (c) pay commensurate with skills and abilities, (d) the opportunity to demonstrate skills and abilities, and (e) job security (SHRM 2019). The next section covers examples of strategies of talent management and employee engagement to improve retention.

Examples of Strategies

Employee perceptions of the decision-making process within an organization can be directly linked to the levels of trust and respect an employee may have with both their supervisors and organization representatives. Perceptions of fairness can be improved with fair compensation for work but can also be increased through open communication channels between worker and management, recognition of good work, and opportunities to develop and grow within an organization, which can convey job security to an employee. Distributive justice, or perceptions about the fairness of organizational decisions, as well as procedural justice, which is the perception of fairness of the process through which organizations make decisions, can reduce counterproductive work behaviors. In a study by Spector (1997), it was found that deviant behaviors such as theft can arise from feelings of frustration within an organization, in reaction to low

perceptions of fairness or representation in the decision-making processes. In addition, it has previously been found that inadequate communication resulted in increased rates of theft and greater amounts of turnover (Greenberg 1990; Ralph and Holmvall 2016). These findings suggest that increasing employee job satisfaction is a crucial step in personnel security for improving retention rates of employees and reducing counterproductive work behaviors detrimental to the organization.

Improving the relationship between employees and supervisors and thus increasing leadership effectiveness is another strategy to improve job satisfaction and, therefore, reduce turnover. Specifically, behaviors such as monitoring employees and providing consequences, providing opportunities to discuss evaluations, giving personalized feedback, giving positive comments about work, and helping employees with goal setting are examples of actions that leaders can engage in to improve job satisfaction of employees (Komaki 1998; Komaki and Minnich 2016). Komaki and Minnich (2016) found that such behaviors led to an increase in job satisfaction, which resulted in improved organization climate and an increase in intentions to stay with the organization.

As previously mentioned, skill utilization has a negative relationship with turnover intentions (Nelissen et al. 2017). An additional benefit of skill utilization is that it is highly correlated with job satisfaction (Humphrys and O'Brien 1986; Tian et al. 2018). Therefore, focusing on developing employees and providing them opportunities to utilize their skills will lead to greater rates of job satisfaction and retention within an organization. Monitoring and developing skills of employees also provides opportunities for managers to provide contingent consequences that have been found to improve employee satisfaction (Komaki 1998; Komaki and Minnich 2016).

An additional strategy to improve employee retention is to measure employee job satisfaction and organizational commitment continually. An annual survey on either of these facets may not be frequent enough and allows employee information regarding satisfaction and organizational commitment to go unaccounted for if they leave the organization (Lee et al. 2018). While it is possible that an organization can develop its own measures of job satisfaction and organizational commitment, measures are also available in both the academic literature (e.g., Minnesota Satisfaction Questionnaire, Weiss et al. 1967; Organizational Commitment Scale, Meyer et al. 1993) and from companies specialized in developing these assessments. Monitoring changes in employee commitment and satisfaction more consistently and continually will allow for quicker identification of turnover intentions in an organization. Being able to adapt swiftly to data collected from organizational commitment and job satisfaction measures will allow for better management of retention in an organization.

Conclusion

Retaining employees in positions that are at higher risks in terms of personnel security is crucial for success of an organization. Improving engagement in the workforce through talent management and increasing job satisfaction are two areas to focus on to improve retention. As the number of job opportunities available and employee turnover increases, strategies to improve employee satisfaction become even more critical. Improving (a) perceptions of fairness, (b) employee supervisor relationships, (c) employee development and skill utilization, and (d) frequently monitoring organizational commitment and employee satisfaction are all strategies organizations should use to improve retention of their employees.

Personnel Security: Selection

Haiden Weaver and Yalcin Acikgoz

Keywords

Selection · Hiring · Validity · Reliability · Background check

Definition

Personnel security selection refers to the methodical process of determining which security position candidates to hire.

Introduction

Personnel selection has, over time, transitioned from an intuitive process based on gut feelings and unsound logic into an empirical process. This process utilizes scientific methods and modern techniques to ensure that an organization makes an objective best fit decision when deciding to hire a new employee or promote from within. Overall, there are three major categories of selection tests that can be performed to evaluate a candidate: classical methods, job analysis-based tests, and security tests. Using these methods, candidates are assessed, and their scores are compared. Depending on the needs of the organization, a selection method is then utilized to determine which candidates are the best fit for the position and organization (Spector 2012).

In addition to poor job performance, consequences of making a bad hiring decision could be hiring an employee who will exhibit counterproductive behaviors such as theft, sabotage, sharing intellectual property without authorization, or even violence, all of which represent a huge cost and liability to the organization (van Zyl and de Bruin 2018). Counterproductive work behaviors refer to volitional acts by employees that potentially violate the legitimate interests of, or do harm to, any organization or its stakeholders (Marcus et al. 2016). However, these risks can be mitigated by having a proper selection battery that includes security tests. The degree to which security tests are utilized in such a battery and the importance placed on them depends on the job offered and organizational requirements. For example, when hiring for a critical position such as a job with access to high-level information, security tests may be given a higher weight.

Additionally, in order to help promote organizational security, the security supervisor of the organization should have an active role during the selection process. The security supervisor may have different titles depending on the type and size of the organization, but they are the individuals responsible for creating and/or implementing security standards and procedures as well as identifying, investigating, and resolving any breaches in security. In addition, security

managers are generally in a position to monitor other employees and customers to ensure safety and security of the organization. Accordingly, it is important to involve the security supervisor throughout the process so that they can better contextualize selection battery responses to identify candidates who may potentially pose a threat to the organization (National Center for O∗NET Development 2018). Regardless of what type of selection test is used, it is important that it is reliable and valid in predicting desired outcomes such as high levels of job performance or a low risk for the organization. A test or method is considered reliable if it produces accurate, reproducible, and consistent results. Similarly, a test or method has validity if it assesses the dimension it is supposed to measure and therefore predicts outcomes that it is expected to predict (Spector 2012).

Types of Selection Tests

When choosing which selection tests to utilize, there are several factors to consider. First, a decision must be made regarding which tests are the most relevant to the position based on the position's regular activities, tools and equipment used, and other job specifications (Doverspike and Arthur 2012). This information should be derived from the position's job analysis. If no analysis exists for the position, one should be performed before selecting a candidate to fill that position (Spector 2012). Since job analysis involves obtaining information about a job from subject matter experts, which may include employees or supervisors working in a job, it is important that the security manager is involved in analyses of security-related jobs. Next, the selection tests to be used in hiring must be determined such that each selection test should measure one or more competencies necessary for that position. Below, each of the three broad categories of selection tests – classical methods, job-specific tests, and security tests – are discussed in more detail.

Classical Methods

Examples of classical selection testing methods include the interview, resume or application review, and reference evaluations. Each of these methods were developed as part of the original intuitive process that used to dominate personnel selection. However, these methods have since evolved into empirical tools that are scientifically developed and used by organizations to make more efficient selection decisions. Part of the reason these methods have remained popular is that they continue to most effectively measure person-organization fit, that is, the degree of compatibility between an individual and the values and culture of the organization (Kristof 1996; US Office of Personnel Management 2019b). Due to these methods being best suited to measure person-organization fit, they are commonly used in the hiring of new employees. However, classical methods still exhibit a useful level of validity in determining person-job fit, which refers to the degree of compatibility between an individual and the tasks and responsibilities she or he must be able to perform as part of the job (Kristof-Brown and Guay 2011). This most commonly takes the form of a structured interview being used to evaluate candidates for a promotion or job change within an organization they are already members of. Interviews can also be used by the security manager as a way to assess a candidate in the hiring process. In this instance, the security supervisor will be able to physically observe the candidate as they provide responses. This provides the security supervisor, through interpreting tone, language, and body language of the candidate, a better sense of it if the candidate may be lying or committing impression management (Sebanz and Shiffrar 2009).

Classical methods, especially the structured interview, demonstrate high reliability and validity for determining if a candidate has the characteristics and values desired by the organization. However, it is important to note that each structured interview will have its own associated validity and reliability based on the questions asked and the scoring system used. Structured interviews ideally must have the following characteristics: (1) the test must include the same set of questions asked to each candidate, (2) the questions must be relevant to the requirements of the job and the values of the organization, (3) the

questions must not involve information protected under the US Equal Employment Opportunity Commission, and (4) answers to each question must be evaluated objectively based on a predetermined system. In addition to higher validity, classical methods are also associated with lower evaluation costs. Cost per candidate refers to the monetary value associated with developing or buying, administering, and scoring a selection test to a group of candidates over the number of expected candidates. The structured interview requires the most intensive development of the classical methods and still presents a relatively small overhead cost. Other classical methods such as the resume or reference review cost little to no overhead. The only remaining cost associated with classical methods is the value of the time used by an employee to conduct the interview or review and analyze the results of the interview, resume/application, and references. The combined aspects of higher effectiveness, determined as a result of a test's validity and reliability, with a low cost per applicant are what make these classical methods still so appealing to organizations (US Office of Personnel Management 2019).

Job Specific

Job-specific tests are the most varied type of personnel selection tests because they are entirely dependent on the job being performed. Examples of job-specific tests are cognitive ability tests, physical ability tests, or work sample tests. It is important to ensure that the person hired is actually capable of performing the job they were hired to do. These types of selection tests are used to measure the capabilities that are found to be needed in a job through a job analysis. These methods were created over time as a result of the development of the scientific nature of human resources management and industrial and organizational psychology. Hence, the purpose of job-specific tests is to scientifically measure person-job fit in terms of whether a candidate possesses the knowledge, skills, abilities, or other characteristics (KSAOs) required for a job. Accordingly, these tests tend to demonstrate high validity for determining if a candidate will perform a specific job well. Other benefits of job-specific tests are that they are the least susceptible to impression management and fake responses, they can be used to provide developmental feedback, and they also provide applicants with a realistic preview of the job (Thornton and Kedharnath 2013). Despite all these benefits, some job-specific tests such as cognitive ability tests can create moderate to high levels of adverse impact, which refers to the problem of producing different results for candidates who are members of a minority group compared to members of a majority group (Oostrom and De Soete 2016).

Job-specific selection tests can be critical in hiring of security personnel. Security personnel are typically hired for either physical security positions such as security guards or for digital security jobs such as an information technology and data security analyst. Though both roles are security oriented, they have different responsibilities and require different knowledge, skills, and abilities. Perhaps more so than most jobs in an organization, it is crucial that security personnel are able to perform their job duties with a high degree of proficiency (National Center for O∗NET Development 2019a, b). Accordingly, it is important that appropriate job-specific selection tests are utilized when hiring personnel for security-related positions.

Security

Security tests comprise the third major category of selection tests and are valuable not just for mitigating potential security risks but also as a valid predictor of the overall job performance. Examples of security tests are integrity tests and background checks. These types of selection tests may provide the most utility in preventing the organization from hiring a high-risk employee, such as one who might steal, sabotage, or become violent. However, other types of selection tests can be adapted to be used as a security test as well, such as an integrity test taking the form of a structured interview.

Integrity tests have good validity in predicting job performance and are consequently one of the most commonly used security tests (Sydell (n.d.)). These are typically applied in a paper-pencil format and include questions assessing attitudes

toward counterproductive behaviors. Low scores on an integrity test are associated with counterproductive behaviors in the organization such as theft, sabotage, disciplinary problems, absenteeism, and even violence. Integrity tests have low levels adverse impact and can be effectively paired with a test that has a higher adverse impact such as the cognitive ability test in order to reduce the overall group differences in a selection battery (Ones et al. 2012; US Office of Personnel Management 2019). Additionally, integrity tests are cost-effective and easy to administer. However, when applied in a written form, integrity tests are susceptible to candidates giving false answers to make themselves appear more favorably, also known as impression management. Even though polygraph machines can also be utilized to assess integrity, they are not allowed to be utilized as a method of employee selection for most private organizations under the Employee Polygraph Protection Act or 1988. Although exceptions exist under this law, these exceptions only cover jobs with government entities, security firms, or pharmaceutical manufacturers, distributors, and dispensers.

Background checks, the most common type of security tests, are implemented by 86% of organizations to find out if candidates have previously engaged in counterproductive behaviors (Aamodt 2015). There are two major types of background checks: criminal history checks and credit history checks. However, the pervasiveness of the Internet is leading some organizations to now use social media as a form of background screening. In addition to these methods, background checks can be so expansive as to include driving records, work history, military service, and education records (Aamodt 2015). This section will focus on the two primary types of background checks as well as the emerging prevalence of using social media as a background screening tool.

Credit history checks are the less prominent of the two major types and tend to include previous addresses, court-ordered judgments, list of revolving accounts with payment history and current balances, and installment accounts with payment history and current balances. This information is always obtained from the same three major credit reporting agencies in the United States. These checks are entirely financially oriented and are typically only administered when the position requires handling large amounts of money or other financial information such as budgeting. Credit checks have high face validity, the degree to which they appear to be effective, for financial positions and serve as a predictor of conscientiousness, responsibility, and some counterproductive behaviors such as absenteeism and theft. However, they have little-to-no predictive validity in determining employee performance (Nielsen and Kuhn 2009). Additionally, an organization must have written consent of the candidate to obtain a credit report. As a result, unless the position has a direct relevance to financial responsibility, credit checks should be avoided as there are more valid, easier, and cost-effective tests that can be administered to measure these traits.

Criminal background checks exist in two forms: candidate self-report on an application and criminal history checks performed by a third party. The time frame for these checks can vary from having ever committed a crime to a crime in the past 5 years, as well as discerning the severity of the crime such as having been convicted of or plead guilty to a misdemeanor or a felony. In both self-report and third-party checks, 58% of organizations report providing candidates an opportunity to explain their conviction and why it should not affect the organizations' hiring decision. While this practice is not legally mandated, it is generally considered a "best practice" (Aamodt 2015). Another best practice is to refrain from performing any background check until a conditional job offer is made. This mitigates the adverse impact of the background check. Criminal history checks have a high predictive validity in determining person-organization fit factors such as conscientiousness and several counterproductive behaviors, despite having little validity in determining task performance (Aamodt 2015).

The social media "background check" is quickly becoming the third major category of candidate history evaluation with approximately

70% of employers using social media to recruit and/or screen candidates and 57% among these reporting that they have not hired someone due to inappropriate content on their profiles (Careerbuilder 2018). Social media sites such as Facebook allow organizations to quickly get an insight as to what type and quality of person a candidate may be, even allowing them to learn information about the candidate that may not have come up during an interview or other selection procedures. However, the information gleaned from this method is often more harmful than helpful. While organizations may feel more secure in their hiring decisions if they can infer judgment about a candidate's character from their social media profile, there is no empirical evidence that supports the validity and utility of this method. Use of social media as a tool to perform background checks only affects the perceived fit and provides no useful information in actually determining a candidate's organizational fit or job fit (Chiang and Suen 2015).

In addition to providing no benefit over existing methods, use of social media to perform background checks can also cause major risks to the organization. The first risk is that using social media as a selection test may reduce the perceived attractiveness of the organization as a potential employer to the candidate and may make a candidate less likely to accept a position (Drouin et al. 2015). The second, and potentially more serious risk, is that using social media as a selection tool can reveal protected information about the candidate, such as race, religion, or a disability, which may have otherwise never have been brought up. If an organization has access to this information, regardless of whether it actually influenced the hiring decision, it can lead to litigation against the organization for discrimination (Van Iddenkinge et al. 2016). This becomes risky as most people have such information publicly displayed on their social media profiles. Many organizations have circumvented this issue by utilizing third parties to screen a candidate's profile and only report back relevant information. However, the cost to do this often greatly outweighs the benefit of the information in the selection process.

Evaluating Selection Test Results

After an organization has determined which aspects of a position they wish to test for and which types of tests to use, developed or purchased those tests to measure the necessary employee qualities, and finally administered those tests, it can begin to analyze the results and find the best candidate for the position. Commonly used methods to make selection decisions include multiple-hurdle and multiple-regression. The process of multiple-hurdle selection involves administering each selection test one at a time, starting with the most cost-effective test first, and then evaluating the results of that test and eliminating candidates who did not pass before continuing on to the next most cost-effective test or hurdle. This process continues until all tests have been administered and a much smaller pool of candidates remain. In this process, it is important to determine a cutoff score for every given test. This cutoff score is the minimum score that can be considered passing. For security tests, this would likely involve a pass/fail decision based on the results of a background check.

In multiple regression, instead of using separate cutoff scores and eliminating candidates by using their scores on each test, a formula is used to create a composite score from each individual test score. This formula is usually generated by applying the selection tests to the current employees and examining their relationship with job performance levels. Then, the cutoff score is applied to this composite score. However, security tests would likely not be included in this formula and still be used on a pass/fail basis depending on the security needs of the organization and the requirements of the job. Both multiple hurdle and multiple regression have been shown to have utility in selection such that using such methods lead to higher scores in the criterion and significant monetary savings resulting from hiring better employees (Ock and Oswald 2018). Among the two methods, multiple-regression approach has been found to lead to higher levels of job performance. However, this does not always translate to bigger savings such that for lower level jobs, multiple-hurdle method was

found to lead to greater cost savings for the organization (Ock and Oswald 2018).

Conclusion

Personnel selection is a necessary process for all organizations, big or small, private or public. With a focus on security in the personnel selection process, this chapter presented the purpose, method, and benefits and drawbacks of the most common types of personnel selection and methods of evaluating those tests available to organizations. Using these evidence-based methods to make employee selections, especially by a security supervisor and for the role of security personnel, organizations are likely to see lower security risks and higher job performance. While there are a number of ways organizations can combine personnel selection tests, what is most important is that the organization achieves the goals it set out to do. With a focus on organizational security, an ideal personnel selection process would be using a security test administered by a security supervisor along with whichever selection tests best measure a candidate's person-organization fit and person-job fit for the specific position. The organization would then utilize the most appropriate analysis method in order to make their final selection decision.

Personnel security · Training · Education · Awareness

Definition

Personnel security training refers to provision of "awareness, knowledge, understanding, and skills needed by any person with the responsibility and authority to perform tasks" (ASIS 2012a, p. 63), which develop and maintain behaviors and competency required for the organization to reach its security program goals.

Introduction

Effective utilization of personnel security as a security countermeasure (Sennewald 2011) requires an organization to "retain and train personnel with the skill, knowledge and ability" to meet its security requirements (ASIS 2012a, p. 59). Training typically has two main foci. First, the organization must determine specific behaviors that facilitate goal achievement, as well as identify behaviors that interfere or interrupt accomplishing these goals (Knowles 1973, p. 129). Second, training aims to improve job performance and thus will include the modification of current behaviors and development of new behaviors that serve that purpose (Nadles 1970, pp. 40–41 in Knowles 1973, p. 98).

According to Physical Asset Protection Standard, "personnel play the most significant part in the success of a security program" (ASIS

2012b, p. 50). Personnel classifications can include visitors, tenants, employees, service providers, and security professionals (ASIS 2012b). The focus of training for general employees is predominantly on security awareness, personnel at every level are involved in some way with the security program and thus require training to achieve security program goals (ASIS 2012b). Security professionals who implement asset protection measures range from security officers to managers, and these individuals require security skills, knowledge, and understanding that provide competencies required in the security profession (ASIS 2012b).

Within the workplace, training is aimed at improving performance through developing competencies or aligning behaviors with the identified requirements of the role. ISO 19011 defines competence as the "ability to apply knowledge and skills to achieve intended results." According to ASIS (2012a) "personnel, competence, and training needs are an output of the context of the organization and its contractual requirements, as well as the risk assessment and definition of objectives" (p. 59). The organization is responsible for identifying training needs and ensuring that all personnel including employees, subcontractors, and other stakeholders are sufficiently trained (ASIS 2012a). The aim of security education, therefore, is "to enable people in our organization to carry out their roles in our security program effectively and reliably" (Roper et al. 2006, p. 2). This entry provides a holistic view of personnel security training including frameworks for training development, relevant topics, and adult learner considerations that support effective learning.

Personnel Security Training

The organization's key groups of personnel requiring security training are general employees and security professionals responsible for implementation of asset protection. Additionally, visitors and third parties may require training. The organization must also consider legal and regulatory requirements which include specifications for personnel security training. There is a common saying that people are the weakest link in a security program, because the effectiveness of administrative and technical controls is limited by the implementation and operation of controls by people. Personnel security, which aims to leverage the human aspects in security countermeasures, is built on the foundation of training as a means to achieve required security performance objectives through personnel. General employees require an understanding of security policies and procedures which they must follow for the organization to achieve security program goals. Security professionals, in contrast, require job-related skills and competencies necessary to implement the asset protection program.

Training for General Employees

Training for general employees provides skills, knowledge, and information to enable understanding of security policies and promotes behaviors that conform to the policies. General employees often have limited background and interests in security.

The Skills, Knowledge, and Information (SKI) methodology presented by Roper et al. (2006) provides a threefold approach to security education, awareness, and training that includes skill, information, and knowledge which are useful for clarifying objectives of security training. According to this method:

- A skill is an ability, usually developed through practice.
- Information is something that can be known: facts, steps in a procedure, and conditions that signal the need for something to be done.
- Knowledge is information that is stored in a performer's brain so he or she can take it out and use it when needed (Roper et al. 2006, pp. 33–34).

Roper et al. (2006) recommend the security educator design training to meet the employees' needs by groups or profiles according to assigned job functions. Often training is the preferred approach to directing and aligning behaviors that

impact security requirements for an organization as noted by Roper, Grau, and Fischer (2006 p36): "The traditional approach to handling a Skills, Knowledge, and Information (SKI) problem is training." Skills, Knowledge, and Information (SKI) provides a focused approach to defining training requirements in terms of skills, knowledge, and information. The Skills, Knowledge, and Information (SKI) method is particularly useful when designing security compliance training for general employees.

A business' ability to meet legal, regulatory, and compliance requirements is one of the most compelling reasons for providing security training to general employees. The main goal of security compliance training is typically to meet and maintain compliance requirements. Puhakainen and Siponen (2010) highlight research findings in the areas of security training and employee compliance including the following considerations which impact the effectiveness of employees' compliance through training. Their seven practical implications are summarized in Table 1. For this type of training to also provide benefits to the organization, the program should be integrated with day-to-day business communications and processes, be continuous, and have top management support. For learners to engage with the material in a meaningful way that can promote appropriate security behaviors, the training should be relevant, facilitate discussion, and consider learners' previous knowledge. The adult learning considerations discussed later will provide more insights as to why it is important to engage adult learners in this way and some suggestions on how to foster a learning environment conducive to adult learners.

Personnel Security: Training, Table 1 Seven practical implications for security compliance training

Organization elements required for successful training program	Use a systematic and continuous training program
	Integrate with normal business communication efforts to integrate security with day-to-day business processes
	Ensure visible support by top management
Training elements required for the training program to effectively engage learners	Take into account the learners' previous knowledge as captured through surveys or interviews
	Include learning tasks that demonstrate personal relevance to the learners
	Use training methods that enable learners' cognitive processing by incorporating cause-and-effect models
	Facilitate employee discussion through educational sessions and active participation in monitoring and reporting of security program status

Training for Security Professionals

Security professionals are employees who directly support implementation of the asset protection program. Security officers carry out specific tasks within the security program, which are documented within the standard operating procedures or post orders. The security supervisor is responsible for overseeing security officers, including their quality control responsibilities. The security manager is responsible for keeping the security program running efficiently and provides direct supervision over the supervisor and officers. The security manager requires not only technical security knowledge but also supervision and management training.

Security officer training is aimed at ensuring individuals have the requisite technical security skills and competencies to carry out standard operating procedures and post orders in addition to generally supporting the objectives of the security program. Pre-assignment, on-the-job, and annual training is recommended for private security officers (ASIS 2010). The Private Security Officer Selection and Training Guideline from ASIS (2010) provides a list of 17 minimum training topics (ASIS 2010, pp. 9–10):

1. Nature and Role of Private Security Officers
2. Observation and Incident Reporting

3. Principles of Communication
4. Principles of Access Control
5. Principles of Safeguarding Information
6. Emergency Response Procedures
7. Life Safety Awareness
8. Job Assignment and Post Orders
9. Employer Orientation and Policies
10. Workplace Violence
11. Conflict Resolution Awareness
12. Traffic Control and Parking Lot Security
13. Crowd Control
14. Procedures for First Aid, Cardiopulmonary Resuscitation, and Automated External Defibrillators
15. Crisis Management
16. Labor Relations
17. Basic Computer Skills

The training topics identified by ASIS include skills typically required by security officers in the conduct of their job. Additional topics may be required depending on the industry and environment where the security professional performs their duties. It is further recommended that "defined training objectives should be based on the risk assessment and facilitate uniformity and standardization of training requirements" (ASIS 2012a, p. 63).

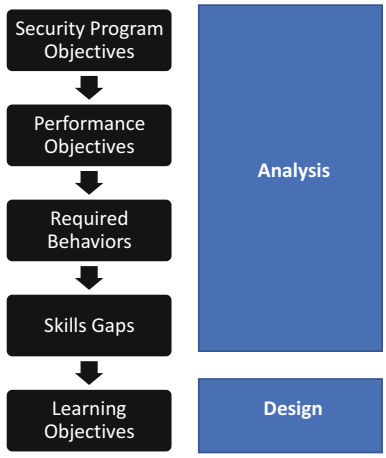
Developing Security Training Programs with ADDIE

Personnel security training should be developed based on best practices in instructional design. Training is developed to address a specific need. The ADDIE instructional design process is a generally accepted approach to instructional design which supports design and delivery of training targeted at diagnosed needs. ADDIE includes the five phases of analysis, design, development, implementation, and evaluation (Chevalier 2011; Peterson 2003). Understanding the ADDIE process can aid training developers in creating an effective security training program. Table 2 summarizes each ADDIE phase and outcome. Analysis involves diagnosing the learning need. In design, the instructional strategy and course outline are created to achieve the learning need. Development is the process of piloting and creating the actual course materials. In implementation, the training is actually delivered via various methods. There are several different approaches and delivery methods including face-to-face learning, online asynchronous and synchronous learning, and videos. The approaches will be determined during the design phase, and training is delivered via the method in implementation. Pros and cons associated with each of the approaches are discussed further in the section on implementation. Finally, in evaluation, feedback to enable continuous improvement is collected from participants.

Personnel Security: Training, Table 2 ADDIE phase outcomes

ADDIE phases	Outcomes
Analysis	Identification of knowledge, skills, and attitudes necessary, training needs matrix, training needs assessment, gap analysis,
Design	Instructional strategy, knowledge-based outcomes, content outline
Development	Training materials
Implementation	Delivery of training materials
Evaluation	Surveys, performance improvement metrics, formative and summative evaluation

Analysis. Analysis requires examination of learning needs in terms of standards and competencies (Peterson 2003). The training need analysis considers training requirements and enables development of the course content. Analysis should be open-ended, considering all possible root causes of the performance gaps, and aligned with human performance training (HPT) ideology. HPT does not presuppose training as the only intervention but considers other non-training interventions that could achieve the required on-the-job behaviors (Abaci and Pershing 2017). The outcome of the analysis phase is clarification of requirements in the training need assessment or gap analysis report. Figure 1 provides an adaptation of Bersin's (2004) approach to aligning training with business needs, simplified with a focus on deriving personnel security



Personnel Security: Training, Fig. 1 Development of learning objectives

learning objectives from the security program objectives.

Design. The outcome of the design phase is content outline, instructional strategies, learning activities, methods, and media which will be used to address the knowledge, skill, and attitude gaps identified in analysis (Chevalier 2011). The learning objectives – "description of a behavior, performance, or skill learners should be able to exhibit following a course or other learning intervention" – are decided based on consideration of skills and knowledge required to perform behaviors (Bersin 2004, p. 28). The course objectives "should be specific and measurable" and become the "landmarks by which you guide the class" (Spalding 2014, p. 40). In this phase decisions are made for the course including instructional, visual, and technical design strategies. The design phase involves planning the schedule of learning which includes determination of the general approach, what will be learned and how much of the material can be covered, and determining how the participants will engage with the material (Rogers and Horrocks 2010, p. 251). Based on the learning objectives and constraints, decisions on the most appropriate methods for learning should be determined based on the course need to employ the following four main categories:

- Presentation methods
- Participatory methods
- Discovery methods
- Evaluator methods (Rogers and Horrocks 2010, p. 253)

Presentation methods include demonstrative teaching activities, participatory methods include interactions between teacher and learners, discovery methods include student learners discovering on their own such as through reading, and evaluator methods are used to evaluate learning such as tests or quizzes (Rogers and Horrocks 2010, p. 253).

Development. The development phase utilizes the outcomes of the analysis and design phases to create training materials, media, and training manuals (Chevalier 2011). Course materials should be developed to elicit appropriate levels of the four phases of learning:

- Activity – doing something
- Reflection – thinking about the experience
- Theory – seeing where it fits in with theoretical ideas
- Pragmatism – applying the learning to actual problems (Rogers 2007, p. 26).

Once materials are drafted, they should be shared with representatives of the target audience for piloting. Feedback from piloting can then be incorporated in the final version of training materials.

Implementation. Implementation involves the delivering of training and providing of appropriate work environment and resources to apply the learnings (Chevalier 2011). There are many methods and media available for delivery of training including the most common approaches of face-to-face classroom, virtual live online classroom, and self-paced online classroom. The decision on approach and methods is determined in the design phase. In implementation the students will engage with the determined methods and media. Bersin (2004) provides a list of various methods and media which may be combined for the delivery of training, and, while the technology continuously evolves, the concepts and approaches remain relevant. In addition to the classroom spaces organized and

controlled physically and virtually by the instructor, global communities of practice are an emerging expansion of learning environments. These communities have been empowered by the ubiquity of mobile technology and "integration of cognitive and social aspects of learning" in the workplace and daily life (Liu 2018, p. 2). Social learning may be facilitated in an organized way through collaboration and hands-on learning formally arranged in online learning spaces (Liu 2018). Informal communities also evolve through professional organizations and other groups that leverage online collaboration platforms. A few of the most relevant methods discussed by Bersin and Liu (2018) are summarized in Table 3, categorized by high-level learning objectives.

There are pros and cons of each delivery method. According to Bersin (2004), when to use the various media types is an important question. Live events whether in-person instructor-led or live e-learning events are more costly however deliver benefits of connections between the learners and instructor. In particular instructor-led training is helpful when:

- Learners are being introduced to brand new material and have no prior experience with the topics.
- Culture building needs are high.
- Direct interaction and discussion with peers and discussion are primary to the learning process (Bersin 2004, p. 145).

Personnel Security: Training, Table 3 High-level learning objectives for the three teaching methods

Gain awareness	Acquire knowledge	Build skill
Webinars Video Blog	E-learning (synchronous, live events, and asynchronous, self-study) Instructor-led training Interactive webinars Written projects	Simulations Service-learning projects Field study projects Game-based learning projects Instructor-led training

The key elements which must be balanced across the different methods are interactivity, cost, and scalability. Instructor-led events are expensive but provide more support to the learner. E-learning is generally more scalable and less interactive unless delivered to small groups and requires some logistical considerations including scheduling and technology access. Simulations and game-based learning require more expertise in the development phase; however it can be scalable and very effective for transferring skills.

Evaluation. Evaluation is used to determine whether the training delivered made the impact intended in terms of achieving the desired outcomes through participants applying learnings and demonstrable changes in behavior (Chevalier 2011). Kirkpatrick's four levels of evaluation is a well-known system of learning evaluation which includes the four steps of reaction evaluation, learning evaluation, behavior evaluation, and result evaluation. Evaluation may include post-training surveys, metrics on performance improvement, and other methods that document the impact training has made on meeting the training needs (Chevalier 2011). The training need assessment in the analysis phase identified requirements, and evaluation validates if those requirements have been met through the implementation of training. The feedback from evaluation should be used for continuous improvement in the training cycle by updating training materials and delivery methods where necessary.

Adult Learning Considerations

Development of personnel security training should include consideration of a best practice for adult learning. The trainer or facilitator is responsible for providing an environment conducive to learning, which includes the space and resources that enable achievement of the learning objectives.

Adult education is not only a means for the organization to achieve its goals through developing competencies of individuals, it also provides personnel the opportunity for self-actualization

through development of competencies which support growth (Knowles 1973). A teaching model is recommended that leverages prior experience, personal motivation, and the problem-centered orientation. Teachers of adults should have attitudes towards the student learners and subject matter which include flexibility and enthusiasm. "Planning skills, communication skills, caring-guidance skills, evaluation skills, and subject skills" must be deployed effectively with an understanding of the philosophy of adult teaching to effectively reach adult learners (Rogers and Horrocks 2010, p. 260). One way to achieve this balance is through teachable moments which provide opportunities for participants to "use their existing experience and knowledge; exercise their learning abilities; and practice" (Rogers and Horrocks 2010, p. 249).

"The best-designed adult learning aims to minimize the disadvantages and maximize the advantages of the experience adults bring with them to learning" (Rogers 2007, p. 35). Current research also supports the need for effective learning to extend beyond dissemination of content knowledge to learning facilitated by "social, cultural, and historical contexts" (Liu 2018). This requires a greater effort on the course developer and facilitators to provide physical or virtual space for positive interaction between participants. In addition to interaction, scenario-based learning is particularly helpful for security professionals. Existing security standards for training recommend practical training including scenario-driven training that models potential conditions security personnel may face in the performance of their job (ASIS 2012a). Developers of security personnel training programs can optimize the learning experience for participants by designing in alignment with adult learning models, while encouraging social learning and scenario-based learning which together support sharing experience and problem solving.

Conclusion

Training is a critical element of personnel security. Providing training for personnel who hold security responsibility and accountability ranging from policy compliance to asset protection develops the competencies, knowledge, behaviors, and attitudes required to meet the organization's security objectives. Personnel security training can leverage current technology to provide multiple methods and media for delivery of training content. Designing training that is relevant for practical situations the learner will encounter with a problem-solving approach is a key requirement whether the target training audience is general employees or security professionals.

In most cases, training for general employees is required annually to meet compliance requirements. This often takes the form of a self-paced online course which is completed along with an end of course test delivered via a corporate learning management system. All employees are required to participate annually particularly for information security courses. Another common approach is to include security training in the overall new employee orientation training. Both of these approaches will require collaboration with the human resources or training department responsible for the learning management system and new employee orientation training. The security manager can also provide general awareness training by departments through arranging with department managers to have security briefings as part of department meetings on an annual or quarterly basis. This approach enables the facilitator to focus on the specific concerns and requirements of the department to make the experience more relevant.

There are several options for security personnel training offered by security professional associations, colleges, and universities. Some states require security guards to be licensed, and those states do have varying requirements for licensing which may include completion of a state-certified training. For those seeking to build a career in security, professional certification is a popular approach as the process to attain certification is rigorous including exams and experience reviews that demonstrate proficiency in the body of knowledge. Many job postings request or require that security professionals have security certifications. ASIS International offers a suite of certifications for security professionals with a range of

focus areas and experience requirements up to and including security management. The International Foundation for Protection Officers offers certifications for protection officers and supervisors.

The security professional often has a critical role in the design and delivery of personnel security training. Depending on resources available, the security professional may even have full responsibility for security training. Even in cases where the security professional is supported by an instructional designer for development of personnel security training, it is important for the security professional to have a basic understanding of instructional design principles such as the ADDIE process and a firm understanding of security program objectives and how they relate to performance objectives and behaviors required. Moreover, the security program objectives must align with the organizational objectives. Where possible it is best to seek support and collaborate with the human resource department to leverage existing expertise and resources for training. The security professional should leverage existing methods of communication in the organization through ongoing collaboration and relationship building with human resources, corporate communications, department managers, and all other relevant stakeholders who can support the program for personnel security training. The personnel security training approach should be integrated into holistic improvement efforts for maximum effectiveness.

System · Control · Diagnose · Inference · Treatment · Professional · Security zones

Definition

Best practice in physical security is the professional use of a systems approach, comprising accurate threat and risk assessments (diagnosis), an aligned protection strategy based on sound theory and security principles (inference), and a mitigation system (treatment) that fulfils operational requirements accordant with legislation, standards, and engineering practice to manage the protection of assets, information, and personnel from damage, loss, or unauthorized access against internal and external threats.

Introduction

It is the duty, as a standard of care, for professionals to exercise diligence in their application of standardized expertise when carrying out work, where professional competence (duty) is judged against the state of knowledge that exists in the form of published methodologies, standards, codes, and research. Consequently, professionals should exercise their professional duty accordant with best practice in order to meet their duty of care obligations in the professional setting.

In considering the public and organizational duty to protect in a professional undertaking, the broad practice of physical security is what many citizens perceive when they consider or pursue day-to-day safety or security, being protected from harm or loss. Physical security includes engineered elements across the built environment that are designed to reduce threats or risks by controlling and managing spatial movement (Parker 2007, p. 233). Therefore, physical security aims to direct environmental control or influence over a defined space. For example, physical security includes protection of the grounds surrounding a facility, and its interior and contents (Fischer et al. 2008). Such control is achieved through the process of layers of physical manipulation measures to mitigate against threats or environmental design facets to reduce opportunistic deviance.

Given the broad usage and associated depth and complexity of physical security's knowledge basis, it is problematic within the scope of this entry to singularly state what constitutes physical security best practices. Consequently, the entry submits that the best practices in physical security must be grounded in the professional application of a defined body of knowledge. All professionals are required to exercise the skill of an ordinary person within their profession when carrying out work. That is, they are bound to exercise due care, expertise, and diligence (Zipser 1999). The professional is deemed to hold both the knowledge (academic basis) and competence to use held knowledge in accordance with the average field practitioner. Competence is judged against the state of knowledge that exists at the time, recognizing that professional bodies of knowledge continue to advance. As Zipser stated, "the professional should be aware of developments which have entered the general corpus of knowledge relevant to their field" (Zipser 1999, p. 4).

Such competence is demonstrated through the conformity to common practice or norms encapsulated within the defined body of knowledge including where available, research findings, published codes, and standards. As such, the inclusive body of knowledge provides a platform for understanding best practice in physical security. A codified body of knowledge has been established for physical security (See Coole et al. 2018). Such codification had synergies with engineering and embodied a matrix of knowledge categories organized accordant to professional practice modalities, including *diagnosing* the security problem, *inference* to reach the optimal

Physical Security: Best Practices, Table 1 Modalities of physical security practice

Modality	Intent	Professional knowledge	Tools
Diagnose	Identify and articulate the problem/s	Criminology theories Security risk Communication	Threat assessment Criticality/Impact assessment Vulnerability assessment Risk assessment Risk context statement
Inference	Defining a mitigation solution from many options in articulating the Security Strategy	Crime prevention Systems theory Defense in depth Deter, detect, delay and response (D3R) Protection in depth CPTED	Situational crime prevention Codes and standards Policy Guidance documents Operational objectives
Treatment	Design, apply and maintain the physical Security Strategy	Physical security Control Response Engineering design	Technical specifications Intrusion detection Barriers and control portals Response procedures System modelling

mitigation among many options, and finally, implementation of *treatment*. Therefore, the entry presents the notion of best practice in physical security through the modalities of a *practice* model. Such a model aligns the body of corpus in which professional duty is judged against the physical security professional tasks of diagnosis, inference, and treatment.

Structure and Application of Physical Security's Knowledge

Best practice in physical security must align with the notion of best practice across other professional disciplines. The modalities model of practice embodying diagnosis, inference, and treatment elements of practice transcend all disciplines and represent a problem focused structure to professional practice (Abbott 1988). Garcia (2008, p. xvii) acknowledged physical security as a problem-centered approach in which understanding and defining the security problem occurs prior to designing and evaluating a protective mitigation system. As Sennewald stated, "security professionals engage in a problem solving process, in which the consultant must first identify the problem(s), gather available data pertaining to the problem(s), analyse that data, and then offer advice in the form of recommendations that will solve, cure, or otherwise minimize the problem(s)" (Sennewald 2013, p. 7). Consequently, the modalities of practice shown in Table 1 represent the most appropriate framework for denoting physical security best practice.

Physical Security Diagnosis – The Problem

Diagnosis is defined as the cognitive task associated with assembling a client's needs (Abbott 1988) or articulating the problem. The body of knowledge associated with diagnosis facilitates establishing the physical protection security threat and risk context. Establishing context has always been an initial component of risk management and includes both internal and external operating context. Context also includes defining the legal context, which outlines required and acceptable behaviors and sets standards. Consequently, in the application of physical security, there are three salient environmental contexts to consider in problem diagnosis:

- Regulatory environment – rules defined and controls directed by a body
- Advisory environment – controls advised
- Self-driven security environment – an industry or organization sets its own risk appetite

Security Risk Management

The professional task of diagnosis is undertaken as security risk management (see ▶ "Fraud Risk Management: Using Fraud Analytics to Combat External and Insider Threats" entries in this encyclopedia), an underpinning activity for all security practice (Talbot and Jakeman 2009; Smith and Brooks 2013). Security risk management incorporates data generated from asset identification and evaluation, threat assessment, security survey and vulnerability assessments, and risk assessment. Consequently, for security to be effective, it must target defined threats.

Informing threat are the theories of Routine Activity, Crime Pattern, and Rational Choice (see ▶ "Security: Theories" entry in this encyclopedia). Routine Activity highlights how movement and activities of both potential offenders and victims relate to targets, motivated offenders, and an absence of guardians interact with intent and capability. Crime Pattern theory highlights the notion that crime fits patterns which can be understood (Lab 2014). Rational Choice theory, as risk management, is predicated on altering the cost benefit analysis of a rationally adversary (Clarke 1980).

For diagnosis, data is analyzed through the process of Security Risk Management, using assessment Standards (ISO 31000 2018; Risk Assessment ANSI/ASIS/RIMS RA-12015) or guidelines (Standards Australia ASHB167 2006). Such instruments are an aide memoire to ensure assessors consider all facts in a logical process; however, they do have limitations including likelihood ratings that are based on averages and biased by perception of probabilities, and consequences remain an estimated variable.

The art of diagnosis therefore lies in defining the real issue (problem). Consequently, best practice in physical security requires a thorough and documented diagnosis of the security risk problem, undertaken to ensure sound strategy can be directly aligned to threat and risk drivers. Diagnosis is communicated, usually in report format, which go by many names including *risk context statement*, detailing the key assets at risk, threat drivers, their consequential risk, and business case to protect, designating contextual degree of protection. Therefore, diagnosis is a clinical judgment that is guided by the presence and relevance of risk factors, historical, clinical, and potential management influences.

Physical Security Inference – The Security Strategy

Inference is focused towards establishing the functions of the protection plan (ASIS International's Physical Security Principles 2015). Professional inference, as a process, may be achieved through excluding what has failed (exclusion) or constructing threat scenarios (construction) relevant to defined threat actors, aligning the mitigation body of knowledge into a systematic strategy. Inference aims to set the security strategy (approach) and operational objectives.

The modality of inference is the use of fused knowledge of security and crime prevention theories and principles along with relevant codes, standards, and guidelines that facilitate the conceptual mitigation of the security problem. The functions of physical security is defined as controlling space, which includes delay, observing an area, situation or event, detecting events, and having an appropriate response to situations. Consequently, it is through the process of professional inference that sound theory and best practice is further layered into physical security best practice.

Function and Components of Physical Security

Situational Crime Prevention. Sound theory embodies numerous theoretical frames including Situational Crime Prevention (SCP), a crime prevention framework of preemptive measures in asset protection. SCP recognizes offenders' cost benefit choices and decisions in offending and presents a rubric of mitigation techniques. These include the objectives of increasing the effort to offend, increase the risks for offenders or reduce their rewards for offending. Such objectives are braced by prevention measures directed at highly specific forms of crime and involve the management, design, and manipulation of the immediate environment in a systematic and permanent way.

Systems Theory. Noting Situational Crime Prevention includes the systematic manipulation

of the physical environment to achieve protection identifies another core theory of physical security, namely, Systems theory. Systems theory is salient within the physical security literature and therefore, of significance for defining best practice. As Underwood (1984, p. x) expressed, security should be designed, implemented, and managed as a system. Such thinking is based on Bertalanffy's (1950) General Systems Theory, which premised that "there are principles which apply to systems in general, whatever the nature of their component elements, or of the relations or forces between them" (p. 139).

Within the physical security context, Garcia (2008) defined a system as an integrated collection of components or elements designed to achieve an objective according to plan. For example, the systematic plan for physical security is to interrupt and, where necessary, neutralize a malevolent adversary before they achieve their goal (Garcia 2008). Consequently, best practice embeds the principles of Systems theory into the protection solution.

Crime Prevention through Environmental Design. The systematic approach to physical security is also embedded into the theory of Crime Prevention through Environmental Design (CPTED). CPTED seeks to extend the notion of controlling people's behavior through natural environmental design and management. The premise draws from both social and physical sciences (American Institute of Architects 2003, p. 40) and is a well-established framework for embedding security strategy into environmental architecture.

Jacobs (1961) contended surveillance provided by legitimate users facilitates the keeping of the peace based on an intricate, almost unconscious, interaction of voluntary and enforced controls and standards by the people themselves. Jacobs coined *Eyes on the Street* to achieve such surveillance. Later, Newman (1972) argued that residential environments can inhibit crime by creating the physical expression of a social fabric that defends itself. Newman (1972, p. 3) defined defensible space as a surrogate term for the range of mechanisms, real and symbolic barriers, strongly defined areas of influence, and improved opportunities for surveillance that combine to bring an environment under control of its residence.

Contemporary CPTED aims to achieve security through reducing opportunities for individuals to successfully engage in deviant behavior (Fennelly and Crowe 2013). CPTED aids the security strategy through using natural surveillance, natural access control, and territorial reinforcement measures, coupled with image maintenance to maintain an expression of defended space. These overlapping and interrelated concepts employ physical and spatial factors, including situational and architectural strategies to ensure environmental context is designed to deter crime while supporting the intended purpose of a space. In many town planning environments, CPTED is captured in jurisdictional Planning Codes and guidelines, and best practice in physical security embeds this theoretical framework into the physical security strategy.

Defense in Depth. Defense in Depth aims to link physical security's functions and elements into a layered protection system to achieve security through interrelating people, technology, barriers, and procedures to achieve a robust physical security system (Smith 2003, p. 8). Such a strategy has been applied to the protection of assets for centuries, based on the argument that a protected asset should be enclosed by a succession of barriers. These barriers restrict unauthorized access to provide time for an appropriate response and recovery (Smith 2003, p. 8). The functions of Defense in Depth elements are:

- Deterrence – psychological measures to deter offenders from deviant acts
- Detection – means to alert that an unauthorized access is underway
- Delay – physical means to retard progress of an unauthorized access
- Response – means of interrupting and neutralizing an unauthorized access
- Recovery – planned approach to reactivating during or after a realized event to return to a priori state

The Systems approach to Defense in Depth interrelates the functions of detect, delay, and

response into an effective security system, referred to as a Physical Protection System (Garcia 2008).

Best practice also embeds well-established physical security principles. For instance, not all areas or protective contexts require the same level of physical security or complexity of system integration. Consequently, physical security strategy requirements are compartmentalized, based on the demarcation and division of space accordant with risk, generally referred to as *security zoning*. Security zoning holds that different levels of protective elements should be concentrated accordant with a cost benefit analysis based on risk. Diagnosis bounds the security assessment and such bounding is used to articulate the environmental limitations of the protection program, setting security zone that focuses the security strategy.

Balanced Protection. Best practice also embeds the principle of layers into the security strategy and includes *protection in depth* within Defense in Depth. This approach includes layering distinct security measures an adversary must defeat in sequence and considers the avoidance of single point failure in any protection plan (American Institute of Architects 2004, p. 11; Garcia 2008, p. 6; Williams 1981, p. 143), considered the "rings of protection" (Higgins 1989, p. 229).

Protection in depth incorporates the design philosophy of multiple detection, delay, and response capabilities (Williams 1981, p. 143; Garcia 2008, p. 6) that complement each other at each layer. Such an approach overcomes individual weaknesses and minimizes the consequences of individual component failure (Garcia 2008, pp. 5–6). The aim is to achieve what Wyss (2009) termed *balanced protection*, achieved when every scenario pathway into a protection environment presents the same level of difficulty.

Best practice within inference refers to setting the protection strategy and supporting operational objectives for the physical plan to achieve, documented as the security management plan. Such a plan is informed by the security risk context and directs the final design and commissioning of the physical security system and program. The security plan establishes the security zones and develops protection objectives to achieve a best practice principles framework within physical security's body of knowledge.

Physical Security Treatment

Treatment constitutes how the security strategy is functionally achieved through the commissioned components of the physical system. Treatment functionally achieves the elements of Defense in Depth including deterrence, intrusion and tamper detection, physical delay, access control, surveillance, and response capabilities (Fennelly 2003; Garcia 2008; Williams 1981). Therefore, treatment draws on a security professional's operational and technical (engineering) body of knowledge. These are applied to system variables as either human practices or individual situational controls, or environmental design measures or interrelated subsystems, combined as a complex physical security system.

In this context, treatment aims to commission the structural or operational components ensuring compliance with the regulatory framework, codes of practice, and other technical specifications to meet the operational objectives set in the inference phase. Such an approach also recognizes the hierarchical structure of complex engineering systems, in which subsystems are themselves comprised of components that are interrelated. At the treatment level, a physical security system constitutes an engineering solution interrelated accordant with scientific principles of analysis and synthesis to understand component and system efficacy.

Best practice applies components and subsystems that achieve the functions of physical security through their ability to collectively deter, or sequentially detect, delay, and respond against unauthorized actions. Treatment elements are evaluated using relevant codes, standards, and defined performance metrics. The use of and compliance with Codes and Standards is well supported in the security literature (See Atlas 1981; Craighead 2003). For example, Atlas (1981, p. 89) highlighted that codes are written as either performance or design specifications,

identifying performance as statements of contextual achievement, for instance, delaying a defined attack type for a defined period, whereas design specifications establish building construction requirements, referencing particular material selection and methods of construction.

Therefore, best practices method in physical security treatment epitomizes the engineering design process, which includes project realization through system definition and modelling, environmental design, product design and selection, component evaluation, installation, integration, and commissioning based on established criteria. Collectively, these processes functionally achieve the security strategy, which must comply with the operational regulatory environment.

Intrusion Detection

The technical subsystem of detection is the Intrusion Detection System (IDS), designed and commissioned accordant with established security zones (see ▶ "Intrusion Detection Systems" entry in this encyclopedia). The IDS is supported by other subsystems, such as active and passive electronic surveillance technologies for assessment and awareness purposes, lighting infrastructure and other security technologies. Also captured within the technological design component is the electronic communications system, which facilitates the linking of human operators and technical componentry. The performance measures for this subsystem draw on various codes and standards within a jurisdictional context, and probability theory calculated as the likelihood of threat detection.

Movement Control

Another technical subsystem of control is the Access Control System (ACS). ACS is used for controlling movement of people and objects, including portal entry and egress, credentials and barriers, and other delay components. Theoretical underpinnings include principles such as credentials that provide something you have (encoded key or card), know (identification code), or are (biometrics) (Smith and Brooks 2013, pp. 159–171).

Response

The situational crime prevention measure or integrated engineered physical protection system are commissioned to facilitate an effective response against a defined threat. Garcia (2008) states this may include immediate on-site response or after the event recovery. Nevertheless, response relates to the performance measures set following diagnosis. The evaluation of on-site response is based on defined performance measures including the denial level and corresponding probability of interrupting and, where necessary, neutralizing the defined threat. Jurisdictional legal frameworks will guide the setting of response standards and therefore, best practice; however, all response behaviors lie on a continuum. Response must be legal and as a minimum considered against a reasonably foreseeable defined threat but may also include extraordinary events.

Modelling Physical Security Best Practice Treatment

Best practices in physical security treatment involve systems modelling, which seeks to develop a simplified, idealized representation that mimics the behavior of the real system to an acceptable level of accuracy (Dandy et al. 2018). Modelling may occur for individual treatment measures or for a large-scale physical protection system, with a focus on evaluation of effectiveness against a defined threat.

Garcia's (2008) publication of the Estimate of Adversary Sequence Interruption (EASI) model for physical security system evaluation highlighted this view into the idea of best practices for physical security. EASI represents a deterministic system, aiming to achieve the same outcome consistently and drawing on probability theory. Such mathematical modelling studies the behavior of existing systems or proposed systems to identify a system state and possible improvements (Dandy et al. 2018).

Physical Security System Management

The physical security strategy is commissioned compliant with performance or technical

specifications in a manner that meets operational objectives; nevertheless, it must be managed and maintained as a system. Therefore, best practices would have physical security managed as a system, based on the efficacy of its objectives being to deter, detect, delay, and respond against defined threats. Consequently, once individual security elements have been systematically commissioned, the measurable processes that ensure efficacy need to be maintained at their commissioning levels. As such, best practice in physical security must also include system decay theory (Coole 2010).

Conclusion

Best practices in physical security draw on its body of knowledge (academic basis) to *diagnose* the security problem, *infer* to set the protection strategy and operational objectives, and *treat* to achieve optimal mitigation with physical components that comply with relevant codes, standards, and guidelines. Diagnosis commences with a threat assessment of adversary groups or individuals, their intent, and capability. Then, a vulnerability assessment ensures that the system is threat driven, supported by risk assessment to understand the significance of the threat within the defined context.

Inference sets the physical security strategy, which demarcates and divides space into *security zones* of protection, sets the level of protection across these zones based on risk (consequences), and establishes system performance measures. Such a security strategy is realized through treatment, where the engineering design process defines the operational standards, facilitates the design and selection of components, their installation and integration, and ultimately their commissioning. However, consistent with decay theory, the system must be managed as an open system, where decay is identified and counted to maintain the security systems commissioned state or updated accordant with the changing threat environment. The benefits for professionals in undertaking their occupational work accordant with best practice is that they will mitigate the threats which pose a risk to the best of their ability within the corpus of knowledge available at that time; therefore, meeting reasonable care requirements under their professional duty obligations.

Definition

Exterior application of physical security entails a system that "integrates people, procedures, and equipment for the protection of assets or facilities against theft, sabotage, or other malevolent human attacks" (Garcia 2008, p. 1).

Introduction

Attention has been drawn to the use of physical security to reduce risks of exposure and consequences of intentional attacks on exteriors. Such measures also can be applied to unintentional weather-related and other natural hazards and accidents. Garcia (2008, p. 2) distinguishes the term security from safety. The term security is restricted to the outcome of "an attack by a

malevolent human adversary," and safety is applied to "the operation of systems in abnormal environments" (Garcia 2008, p. 2). Karlos et al. (2017, p. 3) provide a similar distinction. Dictionaries broaden the definition of security. For example, the Oxford Dictionary (2019) defines security as "The state of being free from danger or threat." The definition implies that physical security can go beyond the more restrictive definition of intentional acts, and though these broader types of threats are beyond the scope of this entry, they are discussed briefly for comparative purposes and for mutual reinforcement.

The concept of physical security in this entry initially addresses prevention of intentional intrusions and is extended briefly to natural hazards given the wide range of attacks society faces from both sources and the fact that many malevolent acts can result in outcomes like those occurring from natural hazards. For example, Garcia (2008) cites fires resulting from terrorist attacks as an example of the overlap. Another example includes floods that result from attacking dams on waterways (see ▶ "Critical Infrastructure: Water and Wastewater Systems Sector" in this encyclopedia). The opposite can also occur. For example, natural hazards can create conditions that lead to malevolent acts of vandalism, where looting has occurred following such events.

Physical security systems are defined by Garcia as physical protection systems (2008, p. 1): a system that "integrates people, procedures, and equipment for the protection of assets or facilities against theft, sabotage, or other malevolent human attacks." The purposes of physical security, regardless of whether the risks, threats, or hazards are natural or human in origin, are those suggested by Garcia for malevolent human actions (Garcia (2008, pp. 2–7): to prevent, deter, delay, divert, or detect movement and reduce damage.

Attacks from intentional and unintentional human actions are of critical concern given what appears to be a growing security problem in terms of the frequency, number of lives affected, and economic impacts of both types of acts. This entry focuses on physical security mechanisms primarily used to address intentional violent human acts that typically involve infrastructure systems. Given the widespread use of infrastructure systems, attacks on them have the potential for significant human exposure. Weaponized vehicles or "vehicle-ramming" incidents that use transportation infrastructure are emphasized here. Klein and Independent Democratic Conference (2017, p. 3) using the Global Terrorism Database cite an increase internationally in fatalities from 10 to125 and injuries from 53 to 523 over the period 2006 to 2016 from "terrorist vehicle-ramming attacks" (see ▶ "Terrorism: International" in this encyclopedia).

Some analogies are also briefly presented for physical protection from natural hazards to compare with intentional malevolent acts and to explore the possibility of synergies for protective measures between them. Cyberattacks against infrastructure are also covered briefly given the increasing incidents in that area especially with respect to new technologies such as autonomous vehicles (see ▶ "Critical Infrastructure: Transportation Systems" in this encyclopedia). Although there are many forms and locations of intrusion, the focus in this entry is on external systems rather than internal or building-related systems though the two may be related.

Attacks that have prompted physical security take many forms that often have different origins and purposes, and security is used to at least reduce the consequences of such acts. The importance of security as a public priority is indirectly reflected in the typically high rank of terrorism among the priorities measured by the Pew Research Center (2019) through surveys, at least for the period 2011–2018 (p. 8; see ▶ "Terrorism: Domestic" in this encyclopedia).

First, the concept of physical security has been introduced and defined in the first section above. Second, examples of the technologies being used, criteria for selection, and selected illustrative costs are provided for different types of security measures. Third, actions that have prompted the use of physical security are discussed, focusing on vehicle ramming. Finally, new directions are introduced including broader economic impacts to diversify physical security measures to support multiple social purposes and to promote soft versus hard physical protections.

Types of Physical Security Systems, Selection Criteria, and Selected Costs

Physical security facilities and systems are generally divided into those that are passive or active (Garcia 2008). Passive barriers are also called inactive, and active ones have been referred to as retractable/moving either manually or automatically (Oakes 2016). There are many support systems accompanying these facilities such as information technologies and electric power that may also warrant security measures (see ▶ "Human-Made Disasters: Electric Power and Transit Linked Outages" in this encyclopedia). Many forms of physical security are used depending on where and what kind of protection is needed. Barriers for transportation systems include, for example, barriers, bollards, and gates. Tables 1 and 2 contain a list of some different types. Extensive reviews of types of physical security facilities exist (Oakes 2016; Hathaway and Hammar 1989; U.S. Department of Homeland Security (DHS) 2010, 2013; U.S. Department of Veterans Affairs 2007).

Selection Criteria

Criteria for barrier selection for physical security depend on the objectives, and these generally include availability, constructability, performance in terms of the ability to withstand impacts, cost, and aesthetics (U.S. Department of Homeland Security 2014). Cost has been a particularly important selection criterion.

Selected Costs

Tables 1 and 2 contain a summary of illustrative costs for passive and active barriers from Oakes (2016), the US Department of Defense (DOD) (1999), and the US Department of Veteran Affairs (DVA) (2007). These sources also provide an extensive list of costs often subdivided by individual components and support facilities by their characteristics. The US DHS (2014, p. 53) provides examples for a "single active vehicle barrier" ranging from $10,000 to $65,000. The US EPA (2004) has also produced cost estimated for security products, primarily for water supply.

Actions Leading to Physical Security

The cases of intentional human actions addressed here are general, unwanted, and often illegal intrusion onto properties usually with the intent to disrupt. Although some are less destructive than

Physical Security: Exterior Application, Table 1 Costs of selected passive barriers (illustrative)

Type of passive barrier	US DOD	US DVA	Oakes
Jersey barrier	$40/ft	$435–915	
Fixed bollard	$600		$2,600–2,800
Fixed bollard: concrete	$520		
Removable bollard			$3,500
Security planter	$80/ft	$690–1,950	

Sources: U.S. Department of Defense (DOD) (1999), pp. 91–92; U.S. Department of Veteran Affairs (DVA) (2007), pp. 3–5; Oakes (2016), pp. 3–4. Oakes data is for equipment costs.
Note: Costs are highly variable, often a function of size and materials. Most of the estimates are for equipment costs only, where the distinction is made.

Physical Security: Exterior Application, Table 2 Costs of selected active barriers (illustrative)

Type of active barrier	US DOD	US DVA	Oakes
General	$9–40,000		
Wedge crash barriers		$71,500–78,500	
Crash barriers		$72,500–101,500	
Raised bollard crash barriers		$24,200–34,400	
Retractable bollards: hydraulic			$40–48,000

Sources: U.S. Department of Defense (DOD) (1999), pp. 91–92; U.S. Department of Veteran Affairs (DVA) (2007), pp. 3–5; Oakes (2016). pp. 3–4. Oakes data is for equipment costs.
Note: Costs are highly variable, often a function of size and materials. Most of the estimates are for equipment costs only, where the distinction is made.

others, they reflect intrusive means that could potentially lead to more destructive acts. The Oklahoma City bombing of the Alfred P. Murrah Federal Building (April 19, 1995) was a key event – a turning point – signaling the need for physical security. The emphasis in this section is on a type of action that has been given a great deal of attention – vehicle ramming. Other intrusions are also discussed briefly, namely, scaling of bridges and cyberattacks, primarily on infrastructure, and their physical security implications.

Vehicle Ramming

Over the course of many decades but most recently since the World Trade Center attacks, vehicles have been weaponized for the purpose of destroying life and property. This is an international phenomenon. Karlos et al. (2017, p. 3) define vehicle ramming as "the use of vehicles (cars, vans, trucks etc.) . . . as a weapon against human targets by terrorists and other type of extremists in their effort to maximize casualties, gain global attention and inflict fear to the population." Karlos et al. (2017, p. 2) estimate that from 2011 to 2017, the number of attacks and the death toll from vehicle ramming have generally increased. They indicate that perpetrators range from single individuals to terrorist organizations and occur at multiple locations with the common denominator being places where relatively large numbers of people congregate (Karlos et al. 2017, p. 2). The potential exists for autonomous vehicles to be used for such purposes, though no cases have emerged.

A number of cases around the world show that vehicles can be used to enter busy sidewalks, cycleways, or public spaces used by pedestrians with the intent of running over pedestrians and cyclists and causing death and injury (Jenkins and Butterworth 2017; Erickson and Stanley-Becker 2017; Ward 2017; Lazo 2017; American Bus Association 2017; Windrem and Arkin 2017).

High-profile cases have been reported in the media in the last few years. Table 3 summarizes

Physical Security: Exterior Application, Table 3 Vehicle ramming examples

Date	City/ country	Description	Injuries	Fatalities
July 14, 2016	Nice, France	A truck was used to attack pedestrians on a beach promenade[1]	200	>80
November 28, 2016	Columbus, Ohio, USA	A car was used to attack pedestrians and the driver then used a knife to continue the attack[2]	11	1
December 19, 2016	Berlin, Germany	A tractor trailer was used to attack pedestrians at a market[3]	48	12
March 22, 2017	London, UK	A vehicle was used to attack people on a bridge and the driver then proceeded to attack security guards with a knife[4]	~40	4
August 17, 2017	Barcelona, Spain	A van was used to attack people on a busy thoroughfare[5]	~80	~13
October 31, 2017	New York City, USA	A truck was used to attack pedestrians and bicycle riders in a walkway/bikeway in Lower Manhattan[6]	~12	8
April 7, 2018	Münster, Germany	A van was used to attack people outside a restaurant[7]	~20	3
April 23, 2018	Toronto, Canada	A van was used to attack pedestrians on a busy street[8]	15	10

some of these attacks and selected impacts. In reaction to such incidents, physical security systems acting as barriers in a variety of forms have been used for prevention. As the size of vehicles used in such attacks increased, other mechanisms have been invoked such as the placement of large trucks, e.g., sanitation trucks filled with sand placed nose to nose to block streets. The use of weaponized vehicles to cause harm in cities around the world has led to the deployment of bollards and security barriers that can prevent vehicles from entering areas that are used by pedestrians and bicycle riders (Quito 2016; Bliss 2017).

Figures 1 and 2 show the kinds of barriers that have been implemented in Lower Manhattan near the scene of the 2017 vehicle attack (Almukhtar et al. 2017). These barriers prevent unauthorized vehicles from entering Hudson River Park, which has a high number of pedestrians and bicycle riders.

Scaling Bridges

Bridge access primarily along cables has become a form of intrusion that is disruptive and dangerous, though generally not resulting in loss of life. Other structures have been scaled as well. Examples of the scaling of bridges in 2014 are given below, a year when several of these events occurred:

- July 22, 2014. Two German tourists/artists scaled the Brooklyn Bridge and replaced the American Flag with a white flag (McKinley 2014).
- August 24, 2014. A Russian tourist scaled the Brooklyn Bridge during the day (McKinley 2014). The response to these incidents on September 2, 2014, was the placement of metal screens on bridge cables as a barrier to intrusions (Morales and Shallwani 2014).
- November 16, 2014. A French tourist scaled the Brooklyn Bridge, climbing over a barrier (Pervaiz 2014).

Physical Security: Exterior Application, Fig. 1 Physical barriers on Hudson River Park near Houston Street, New York City. (Source: Photo provided by Carlos E. Restrepo)

Physical Security: Exterior Application, Fig. 2 Physical barriers on Hudson River Park near Chambers Street, New York City. (Source: Photo provided by Carlos E. Restrepo)

One type of barrier that is used on bridges to prevent scaling incidents is shown in Fig. 3. These physical security facilities are used in conjunction with screens and other types of barriers such as gates to reinforce barriers to access and have been used on New York area bridges; they are considered especially effective when installed at low points in the cables where they are closer to pedestrian paths (Morales 2014).

Computer-Related Intrusions (Cyberattacks)

Computer controls now dominate many physical systems and present vulnerabilities in the form of cyberattacks and other computer intrusions. These have been reported by ICS-CERT for infrastructure disruptions, and some attacks increased between 2011 and 2015 (Zimmerman 2017). Prior to that, simple laptops off-site were used to disrupt infrastructure operations such as spillage of water and wastewater (U.S. Government Accountability Office 2007, pp. 6–7). As information technologies become more common in the operation and control of infrastructure, including vehicles, vulnerabilities to cyberattacks will have to be managed. Many cyber security systems work together with physical security systems (Zimmerman and Dinning 2017).

Analogies from Unintentional Breaches of Physical Security

The challenge that physical security poses is reflected in vulnerabilities that have arisen in the context of unintentional attacks with outcomes like those originating from intentional acts. For infrastructure, intruders accessing infrastructure facilities could cause damages similar in magnitude to unintentional acts. Some examples are noteworthy of unintentional disabling of infrastructure systems from computer failures and natural hazards such as lightning strikes and other weather-related hazards that commonly occur that produced outcomes like deliberate intrusions. Examples of computer failures that have affected rail transportation (Zimmerman 2012) are:

1. On August 20, 2003, CSX rail shut down from a computer system failure (InformationWeek 2003).
2. On May 25, 2006, Amtrak and NJ Transit were disrupted from a failed 4-year-old computer part that provided power restoration orders (Associated Press 2007; Wald 2007).
3. On September 29, 2011, major disruptions of the Long Island Railroad occurred from a lightning strike and the associated failure of a new computer system (Metropolitan Transportation Authority 2011).

Another type of incident occurred in 2007 where magnetic structures were catapulted onto bridges and other steel structures in many US cities resulting in massive shutdowns of infrastructure, and some of those cities were put on alert due to fears of intentional terrorist acts (Chung 2007). The originators were advertisers, law enforcement officials had them removed, and the settlement was cited as $2 million, half of which was for the infrastructure disruptions (Zezima 2007). Although these actions were intentional and did not appear to be malevolent or linked to terrorism, they did point to vulnerabilities in access that are relevant to physical security.

Going Forward: Some Solutions

Information technologies are now used with physical security for protection and these two components need to be integrated with one another. On the one hand, information technologies can enhance and strengthen physical barriers, and, on the other hand, physical barriers are often needed to provide physical support for information technology devices (Zimmerman and Dinning 2017). One notable example is CCTV used to detect perpetrators. It was used to identify London train bombers in 2004. The deployment of CCTV is often flexible, for example, it can be mounted on physical rail transit structures (see ▶ "Rail (Train) Security" in this encyclopedia).

Physical security barriers can be coordinated to address multiple threats that have similar outcomes. Protection systems for natural hazards

share some similar purposes in common with security threats. Examples of technologies used for natural hazards involved in flooding are designed to seal off areas from water impingement. Examples range from sandbags, "Hesco" baskets, and "Tiger Dams" at relatively smaller scales to massive flood walls and massive instream barriers such as the Thames Barrier. These structures also at least reduce or complicate access by malevolent actors. In the aftermath of Superstorm Sandy, for example, a project in Red Hook, Brooklyn, is contemplating using barriers that are designed to serve multiple purposes. These barriers can help reduce flooding, create green space, and house battery storage capacity that can provide electricity when there is a blackout (Rosenberg 2017). These barriers could also be designed to support backup services for other critical infrastructure systems such as telecommunications. This type of barrier design suggests that such structures can serve multiple goals and can contribute to improving safety and security during extreme weather events.

The implementation of barriers has costs and benefits. These can be difficult to quantify. The most obvious benefit is that they can prevent something like a vehicle attack. However, once barriers are implemented, it is difficult to measure the impacts they may have helped to prevent. Another benefit is that pedestrians and bicycle users may feel more comfortable using sidewalks, parks, and bikeways if they see security measures in place. On the other hand, using barriers in dense urban environments can be a nuisance to pedestrians and bicycle riders trying to navigate busy sidewalks and bikeways. These kinds of barriers can also make it difficult for local authorities to use maintenance, security, and emergency vehicles in areas where they may be needed.

A 2012 study used a large-scale infrastructure construction project to assess whether the use of barriers had significant economic costs in a neighborhood (Zimmerman and Restrepo 2012). The study used large physical barriers and structures deployed during the construction of the Second Avenue Subway in Manhattan to understand potential costs related to housing and business activity. A literature review suggested the barriers and disruptions had a negative impact on rents close to these structures. However, the authors looked at the assessed property values of a random sample of buildings in the area and compared values before and after the beginning of the construction project and found no significant impact on this measure. Extrapolating the kinds of costs associated with large-scale construction projects to physical security barriers has some limitations since the former tend to use much larger barriers and structures.

In response to environmental and social concerns associated with hard physical barriers, softer approaches to protection have emerged. Hard infrastructure has been considered a contributor to increased vulnerabilities for natural hazards (Logan et al. 2018). For natural hazards, green infrastructure has been promoted for many purposes such as absorbing water, pollutants, heat, etc. The concept of water-absorbing structures has been popularized in the Netherlands, among other places throughout the world. Water tunnels that act to channel road traffic during dry weather and water in wet weather have also been introduced, for example, in Kuala Lumpur, Malaysia (Zimmerman 2012, pp. 115, 149; ITS International 2012). Parkland has provided an outlet for combining environmental protection and social goods as an alternative to physical structures (Beitsch 2019).

Similarly, for physical security, traditional hard barriers have been designed for aesthetic and recreational purposes. Physical barriers can be used in combination with other measures to improve security. These include landscaping to create green buffers between streets and sidewalks and creating auto-free areas in parts of cities with high numbers of pedestrians (Ventiere 2017; Garfield 2017). In addition, information about traditional vehicle collisions with pedestrians can help transportation and security planners identify areas where pedestrians may be at risk and where physical barriers can reduce harm.

Conclusions

Physical security is a very real need given the numerous incidents that have occurred, many with severe social consequences not only as direct

loss of life and injury but also the often difficult to estimate psychological toll. Physical security is often an initial response to intentional acts as it is with other kinds of threats posed by natural hazards. Ways in which protection for multiple hazards can be provided are important considerations given the very large investment often required to support such security measures. Also, a very important direction is to promote ways to provide socially beneficial uses of such barriers, for example, for aesthetics and recreation.

Physical Security: High-Rise Residence and Office Buildings

Seungmug (Zech) Lee
Department of Criminology and Criminal Justice, The University of Texas at Arlington, Arlington, TX, USA

Keywords
High-rise/tall building · Risk assessment · Security · Security for high-rise

Definition

High-rise security refers to a specialized but comprehensive safety and protection approach to prevent, mitigate, minimize, and respond the possible danger and emergency situations to life and property for occupants who reside and/or work in multistory buildings from various natural and human-made threats. Security professionals' predominant areas of responsibilities include lobby concierge, operating and monitoring CCTV, screening visitors and client employees, building inspection, and access control.

Introduction

High-rise buildings provide numerous benefits (e.g., a large amount of living, working space on a small land footprint, and reduction of the costs of providing utilities and services) to residences and offices in urban settings, but such benefits come with security and safety issues and challenges. Since they occupy small and size to erect the structures to reach multiple floors, easily from over 10 stories to near or sometimes over 100 stories, high-rise buildings are by and large tall and closed off all sides with a lot of individuals as either residents or office occupants and diverse activities. Unlike low-rise structures with 1–3 flat buildings, such tall high-rise ones are vulnerable to natural or man-made disasters (e.g., earthquake,

fire, power outage, equipment malfunction, and so on) (see a series of ▶ Human-Made Disasters: Toxic Waste and Residences in this encyclopedia).

To protect the lives and property of the multitudes of people who daily use these facilities, it is essential that high-rise security programs and practices are well planned and executed. Security professionals responsible for the safety and protection of such buildings should ensure that appropriate services and programs are in place to protect residents, office occupants, and the property inside.

This entry will discuss the definition and types of high-rise buildings, security challenges, security issues/threats, security responses, and risk assessment for high-rise buildings.

Types of High-Rise Building

A high-rise building is a tall multistory structure. It can include the following aspects: first, any structure where the height can have a serious impact on evacuation; second, for most purposes, the cutoff point for high-rise buildings is around seven stories; and third, a high-rise structure is considered to be one that extends higher than the maximum reach of available firefighting equipment, which can vary between 75 feet (or 23 meters) and 100 feet (or 30 meters) or about seven to ten stories. The exact height above which a particular building is deemed a high-rise is specified by fire and building codes for the country, region, state, or city where the building is located. Elevators are used as a vertical transportation system, and some utilize escalators to move people between lower floors (Ahrens 2016; Craighead 2009).

Since the late 1800s in the USA, high-rise structure developments have dominated major city skylines for office buildings, hotels, and residentials with the help of safety elevator and steel frames. For example, there were two major eras for erecting the tallest buildings – the early 1930s for the 77-story Chrysler Building and the 102-story Empire State Building and the early 1970s for the 110-story Twin Towers of the NY World Trade Center (WTC) and the 110-story Sears Tower in Chicago. However, since themed-1990s, the new wave of the high-rise building constructions has been on virtually all continents of the globe simultaneously, resulting in ever-denser, ever-taller cities from Moscow to the Middle East, from Shanghai to San Francisco with new security and safety challenges. It is not only the height and geographic spread of tall buildings that have changed but also their types and materials used to construct. Whereas historically the world's tallest buildings have been dominated by office buildings, were built of steel, and were built to project the prowess of an individual corporation, many of the world's new supertalls now contain residential or mixed-use functions, use concrete and composite construction, and have been built to project the vitality of a city on a global scale (Challinger 2008; Craighead 2009).

Most high-rise buildings can be categorized based on their primary purpose – office buildings, hotel buildings, residential buildings, specific-purpose buildings, and mixed-use buildings. An *office building* is a structure designed for the conduct of business, generally divided into individual officers and offering space for rent or lease. In the commercial high-rise buildings, occupants are office workers, visitors, and facility management staff. The term "hotel building" is an all-inclusive designation for facilities that provide comfortable lodging and general food, beverage, entertainment, other "away from home" services, as well as a businesslike environment. There are also hotels that contain residences, known as hotel residences. A *residential building* contains separate residences where a person may live or regularly stay. Each residence has independent cooking and bathroom facilities and may be known as an apartment, a residence, a tenement, or a condominium. Examples of high-rise residential buildings include apartment buildings and student dormitories in urban settings. Occupants are residents, visitors, and building support staff. *High-rise specific-purpose* buildings include hotels, hospitals, educational facilities, retail malls, prisons, and car parks. A *mixed-use building* may contain offices, apartments, residences, and hotel rooms in separate sections of the same building (Ahrens 2008; Challinger 2008; Craighead 2009).

Security Challenges of High-Rise Buildings

There are several reasons why high-rise buildings have become popular among the nations in the world. First, the exploding population in largely urban settings creates an increasing demand for high-rise buildings. Arable land areas are gradually being eaten away by urban spreading through suburban developments. The high-rise building can accommodate many more people on a smaller land than would be the case with low-rise building on the same land. Second, it is generally acknowledged that there has been evident neglect of the human factors in the urban design at the expense of livability and quality of life. The outward expansion of cities into the suburbs has resulted in increased travel time and traffic gridlock. Clustering of buildings in the form of high-rise buildings presents an opportunity for creating open recreation for playgrounds, plazas, parks, and other community areas by freeing up space at the ground level (Craighead 2009).

Some characteristics of high-rise building structures are related to the unique security challenges to security professionals and their operational management, including size, location, anonymity within the building, building contents, occupant characteristics, and physical features (Challinger 2008). For example, due to their *size*, high-rise buildings or very tall buildings can be iconic and targets for security breaches. However, their size may also slow down security response in the case of man-made or natural disaster situations. A good example was the old World Trade Center twin buildings in the Lower Manhattan. It became the first target by 9/11 terrorists. *Anonymity* within the building is an inevitable feature which may make it difficult to tell whether people in a high-rise building should be there or not. They could be legitimate occupants or visitors, and among them a potential offender may not look out of place. Anonymity in a high-rise building may lead to a "not my problem" attitude, making it easier for a criminal to operate unobserved.

Another security challenge is *building contents*. A high-rise building generally provides a concentrated volume of property, making it an attractive target for criminals. Much of that property could be described as CRAVED, an acronym for "concealable, removable, available, valuable, enjoyable, and disposable" (Clarke 1999; Petrossian and Clarke 2014). In commercial buildings, some corporate officers feature expensive fittings and high-value art. Property in upmarket residential buildings also tends to be of high quality. High-rise building *occupants* may not all have the same exposure to or concern about security problems. A tall commercial building may be occupied by low-risk tenants, along with high-risk ones (e.g., controversial or high-profile companies, political organizations, and government offices). High-rise residential buildings may have a mix of owner-occupiers, rental tenants, and public housing residents.

Physical features of a high-rise building provide opportunities for such offenses as elevator crime, stairwell crime, and window crime. Surveys indicate elevator crimes and breakdowns are among the top five concerns of high-rise residents. Most elevator crime seems to comprise personal offenses such as robbery or assault. Stairwells in high-rise buildings are invariably enclosed because of construction codes. They provide another site for robbery and offer escape routes for offenders. Lobbies, corridors, and outside plazas, since they are common areas, often have no specific owner or guardian to help prevent crime and disorder. Windows, if openable, may allow access by cat burglars. People may throw objects from windows, causing criminal damage to any passerby or car parked down the street. In a worst case, a window could be used by a sniper. An example was the Las Vegas mass shooting incident on the night of October 1, 2017. *Locations* are also a security challenge. Many high-rise/tall buildings are located in central business districts in major urban cities. Their proximity to mass transit facilities and ease of access to the general public puts them a particular risk from professional criminals.

Security Issues/Threats

High-rise buildings, just like any other built-in environments, have several security threats.

Some can be observed just like any other built-in settings have; however some are unique to high-rise building atmospheres. Examples of the major security threats surrounding high-rise buildings are crimes, disorder, and building emergencies (Challinger 2008; Craighead 2009; Office of the Fire Marshal 2002; Savage 2005).

Crimes are probably the first security concern for high-rise security professionals. Several criminal behaviors around the high-rise building perimeter are (1) theft and burglary from private spaces, car parks, and delivery docks; (2) property damage, such as graffiti and sabotage, most likely in common areas or car parks; (3) offenses against persons, including general violence, domestic violence, elevator assaults, and confrontations in common areas, such as angry interchanges with doormen or receptionists; and (4) unauthorized access to utilities, including theft of telecommunications or electricity with the possibility of commercial espionage.

Disorder is another security threat for high-rise building security. Disorder behavioral issues include drug dealing from the building, hostage-taking, trespassing, suicide risks, protests, and drunk or drug-affected disorderly conduct in and around the buildings.

Two *building emergencies* become a critical aspect of high-rise building security operations – human-caused and natural disasters. The former includes fire/explosion, bomb threats, biological and chemical threats, suspicious package, infrastructure and elevator failures, electricity blackouts, hazardous materials accidents, and terrorist attacks. The examples of the natural disaster are weather events such as earthquakes, floods, tsunamis, hurricanes, tornados, and snowstorms with heavy snowfall.

Security Responses

Several common security responses for high-rise building structures include diverse security practices, including access control, physical security measures, CCTV (closed circuit television), security officers, security and emergency plans, and occupant involvement (Ahrens 2008; Challinger 2008; Fischer et al. 2019; Savage 2005; see ▶ Physical Security: Video Surveillance, Equipment, and Training in this encyclopedia).

Access control is the primary security practice for a high-rise building. A tall building has the restricted number of entry points from outside, which can direct security team to control better access by people, vehicles, and goods. An access control system combined with alarm capacity and CCTV is the most frequently used security measure in high-rise buildings. The level of access control depends on the major business activities of, the function of, and the volume of both human and vehicular traffic of the building. For example, access to building structures housing sensitive government departments may be highly restricted, whereas general access can be given to visitors at hospitals. High-rise residential buildings may have restricted access control practices. Advanced technology has been integrated into automated access control systems for more effective and efficient practice. Vehicle access in high-rise buildings to parking areas is generally automated, though still some buildings station security officers to check and direct in-and-out vehicular movement. Deliveries to high-rise/tall commercial and residential buildings are controlled and channeled through one access point with a security officer loading dock with CCTV monitoring.

Physical security measures are also used in high-rise buildings as a target hardening method, including locks, reinforced doors and windows, intrusion alarms, lighting, perimeter gates and fences, barricades, and bollards. *CCTV* is widely utilized in high-rise building structures with technological advances. For example, Internet-based CCTV which can be integrated with motion detectors and alarm systems can allow occupants to view movements in tall buildings remotely. *Security officers* are still quite common practice in high-rise office and residential buildings. Uniformed security professionals stationed at the main entrance provide the first line of access control function. They can check all visitors, patrol the perimeters, supervise vehicle traffic and access, monitor CCTV control rooms, and respond to emergencies.

Security and emergency plans are an essential part of security responses in high-rise buildings. In most cases, such plans and procedures are mandated by local security and fire safety regulations with the requirements of fire alarm systems and fire drills with evacuations. Particularly, fire evacuation plans are critical for high-rise buildings where the fire service may not be able to reach higher floors in case of fire with their rescue equipment. *Occupant involvement and awareness* is another critical safety response in high-rise buildings. A security staff needs to communicate effectively with occupants in the buildings for emergency plans by means of mailings, websites, elevator bulletins, email, or meetings. Security training and awareness programs can lead to increased natural surveillance among occupants.

Risk Assessments

Security and life safety needs in high-rise buildings should be determined by identifying specific assets and threats against those assets. An important tool for determining such needs is a risk assessment (Craighead 2009; NIST 2005). *Risk assessment* is the process of identifying internal and external threats and vulnerabilities, identifying the likelihood of an event arising from such threats or vulnerabilities, defining the critical functions necessary to continue an organization's operations, defining the controls in place or necessary to reduce exposure, and evaluating the cost for such controls. Risk assessment can utilize security survey and fire prevention survey.

A *security survey* is an exhaustive physical examination of the premises and a thorough inspection of all operational systems and procedures. It may focus on different aspects of a high-rise facility, including the area and businesses in the surrounding neighborhood, the building itself, a particular tenant or resident in the building, or defined aspects of the security operation such as policies and procedures, systems, and equipment. Using a survey checklist of areas to be covered, a security survey should include interior spaces of high-rise buildings, building perimeters, and surroundings. A *fire prevention survey* has similar objectives to a security survey, aiming to ascertain the present fire safety status, to identify deficiencies or excesses, to determine the fire safety protection needed, and to make recommendations to improve the overall safety of high-rise building under evaluation (Craighead 2009, Fischer et al. 2019; see ▶ Fire: Prevention, Protection, and Life Safety in this encyclopedia).

Risk assessments are invaluable in helping high-rise building owners, managers, security and safety directors, and consultants effectively and safely operate tall buildings and thereby reduce premises liability. To identify specific assets and the threats to these assets, assess vulnerabilities or weaknesses to such threats, and devise measures to counter such weaknesses, the security surveys and fire prevention survey are an essential tool. To conduct a thorough analysis of a facility, it is helpful that it be carried out in a methodical fashion.

Conclusion

Since their first appearance during the end of the nineteenth century, the design and construction of high-rise buildings have changed significantly in cities. A boom in high-rise/tall building construction and the use of them impact their security and protection needs, depending on different types of building structure and occupancies. Current security measures include access control, physical security, CCTV, alarm systems, lighting, security officers, emergency plans, and documented procedures. Still, crime, disorder, emergencies, and fear surrounding high-rise buildings are constant issues for security practitioners. There might be no perfect security and safety measures for such high-rise building structures. However, a well-conceived security program will effectively prevent potential security problems, mitigate once an incident occurs, and recover from loss and damages. Such a program should be a comprehensive approach with the aspects of physical security and procedural security and cooperation among occupants.

Definition

Access controls are the mechanisms that monitor, prevent, and control access to essential resources, from buildings and garage doors to network data repositories.

Introduction

As technology becomes increasingly pervasive, access controls are everywhere. Examples of access controls include the use of access cards to gain entry into controlled areas, buildings and parking spaces, the use of biometric authentication to access cell phones, and the use of online credentials to access social media like Facebook and Twitter and credentials required to gain access to work computers.

Access controls are categorized into two types, logical and physical. *Logical access controls* feature connections using hardware, software, identification protocols, authentication, authorization, and accountability (audit), to allow access to a computer system and/or a network resource. *Physical access controls* refer to access to buildings, rooms, and control gates. These controls use key fobs, access cards, mobile device applications (apps), and other tokens to allow access to these areas.

This chapter focuses on *physical access control mechanisms*, specifically their description and functionality, credentials, basic components, system topology and standards, security concerns and risks, system adaptability, and best practices in choosing a system. In conclusion, the chapter describes best practices for maintenance of physical access control systems and suggests that the success of an access control system depends upon its ease of use, communication with and training of users and administrators, integration with other systems, and timely software and security updates.

Main Access Control Components

Keys and locks are the ancestors of modern access control systems. The oldest known lock and key were discovered in the ruins of the palace of Khorsabad near Nineveh (Encyclopedia Britannica n.d.). It dates back to about 4000 B.C. and belongs to the Mesopotamian kingdom of Assyria (de Vries et al. 1993). The lock and key spread to ancient Egypt, then ancient Greece, and ultimately to the Roman Empire.

Today, thanks to the arrival of smart home kits and the Internet of things (IoT), the modest key and lock are becoming obsolete. Computer-based devices that transmit, collect, and share data over the Internet autonomously are quickly replacing them. These include smart home devices like smart locks, which are residential access control systems, smart thermostats, smart light bulbs, and smart security camera systems. A smart lock can replace a front door's key. It can remotely lock and unlock a door, track who enters and leaves, and allow access to visitors. In addition, smart locks and other IoT devices, such as smart security camera systems, can interact with smart home ecosystem and thereby provide a broader home automation.

An enterprise access control system is a more complex and elaborate system that can grant access at multiple entry points and can manage hundreds or thousands of users' access credentials. This kind of system can provide a history of events, a real-time audit trail, and can be integrated with intrusion systems, security surveillance systems, and visitor entry systems.

In an access control environment, an access point may be a door, gate, closet, or an elevator door where the system permits access. A cluster of access points is called a zone. A zone may be used to manage a number of doors in a floor or a building. For example, in a hospital environment, a pediatric floor might have 40 different door types, and all may be managed by a single pediatric zone.

Access Control Software

Access control software is the heart of every meaningful system. It handles a large number of access points, zones, different user levels, calendars, time periods, and time zones. The user interface is handled by web-based software (client-based or web-based applications) that can be accessed from any workstation with the right credentials. Since the application is web-based, the interface between a user and the software may be accessed using the Internet or an intranet through a browser. The access control database or access control list (ACL) resides on a server and is accessed over a network.

Control Panel or Controller

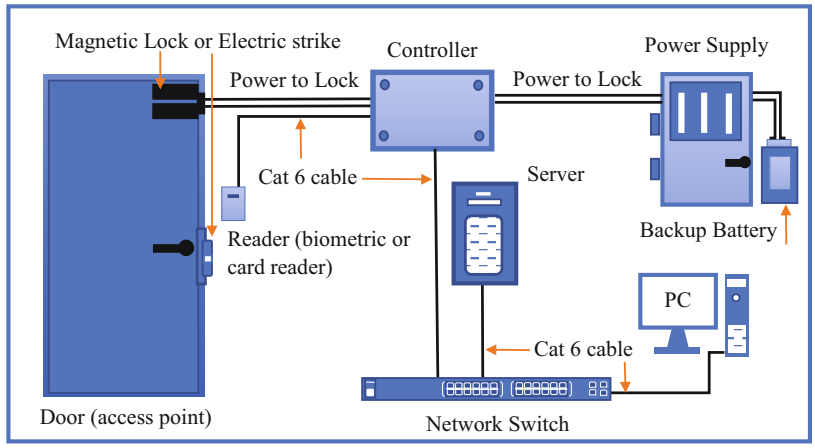
The control panel (controller or control unit) sends the lock a signal to unlock the door when it receives the request from the reader. It then verifies the request with the user's credentials, and if the credentials match, the controller signals to unlock the door (see Fig. 1).

Credentials

The user's credentials in an access control system represent the modern key that allows admission to an entrance. The credentials vary, depending on the user's level of security and level of usage. Credentials may be proximity cards, key fobs, bracelets, mobile apps, passwords, and biometric credentials. In the area of physical security, the most common credential is the RFID card (Bacco et al. 2017).

Locks

The locks (magnetic locks, wireless locks, electric strike, electric mortise door lock, etc.) are the



Physical Security: Interior Applications, Fig. 1 A typical access control setup with the most basic components

essential elements that electrically unlock or lock access points. These different types of locks serve different purposes. Every lock that is not wireless has a wire that supplies power and connects back to the control panel. Wireless locks can be cost-effective and convenient in comparison to wired installations. The disadvantages to wireless lock systems are the cost of their maintenance, for example, updating drivers and replacing batteries. Furthermore, certain locks open spontaneously when electricity is delivered, and certain locks will lock automatically when electricity is suspended. In the event of fire, some locks (front entrance, hospital exit doors, etc.) should open automatically to comply with fire and safety codes and to allow personnel to exit the building during emergencies. A unique lock is the magnetic lock or maglock that uses electromagnetism to control the *locking* apparatus attached to the door and doorframe. This type of lock is used at high traffic and emergency exits that utilize fire safety applications. The appropriate lock to install depends upon the door type and requirements, the location, and the construction material (see Fig. 1).

Readers

Users must employ a reader (biometric, card reader, or keypad) as the first tool to access an entrance. The typical reader scans their credential and sends the request for entry to the controller; it is then sent to the server for authentication. It is the access control database, not the reader that decides whether access is permitted or denied. A combination of readers may be used for additional security (see Fig. 1).

Some readers, especially wireless readers, are built into wireless locks and have their own Internet Protocols (IP). These are used as independent systems and do not communicate with any controller, but instead communicate first with the router and then with the server, which connects via Ethernet or Wi-Fi. Biometric readers utilize mature technologies and are popular with access control systems. Biometric readers identify and authenticate a user based on physical or behavioral characteristics (also known as modalities). Biometric readers can use biometric fingerprint scanners, facial recognition, iris recognition, palm vein recognition scanners, retinal scanners, and voice patterns (Nemeth 2017). However, biometric readers can err by failing to authorize a genuine user. Purchasers should be wary, examining false acceptance rates (FAR), false rejection rates (FRR), accuracy, and anti-spoofing capabilities such as parody and forging.

Exit doors usually employ one reader and a "request to exit" device that allows a person to exit freely, when the user has entered the facility using a credential. The exit device can be a push button or infrared (IR) technology used to request egress by motion detector, which releases the lock. The device communicates with the access control software and instigates free egress. This is an important feature for meeting fire safety code requirements. Access control systems and

more specifically controllers are usually linked to fire alarm systems. In addition, all access points, along with their controllers, readers, request to exit devices, and locks should be equipped with a 4-h backup battery (Norman 2011) and should be connected to a backup generator.

Access Control System Description and Functionality

Description

An access control system allows the end user to manage and screen access to a particular area, entry or exit point in real time. In some cases, for example, in restricting access, companies and agencies are required to adopt access control systems as part of regulatory compliance. Hospitals are required to comply with state, local, and federal requirements like the Health Insurance Portability and Accountability Act of 1996 (HIPAA), as well as with requirements set by independent, not-for-profit organizations like the Joint Commission for Regulatory Compliance. Additionally, some companies must comply with security-conscious businesses compliance regulations (SOC2) or comply with Security Council standards (PCI). Access control systems provide quick and convenient entree or exit to authorized individuals, as well as audit trailing, real-time monitoring, remote accessing, and restriction of entry to unauthorized individuals.

Access control systems can monitor a great number of access points in a building and around its perimeter, including facilities, doors, electronic gates, locks and cylinders, workstation access, data center racks, printer access, furniture and cupboards, and letter boxes as well as lockers. The system can provide sophisticated security by controlling entrances and exits or do a simple task like opening a locker. Furthermore, a good access control system excludes intruders and provides real-time event-driven activity monitoring and early warning.

Access control credentials will vary depending on the level of security and the relevance to the job. In a more secure area like a data center, security requirements are increased; users require a combination of credentials, for instance, a proximity card and a biometric reader. In addition, the choice of biometric reader will be considered carefully, based on the error rates that can emerge, like FAR, FRR, accuracy, and anti-spoofing capabilities, such as impersonation and counterfeiting (Araújo et al. 2005). Furthermore, additional scrutiny is needed if the system is operating in a high traffic area, like a hospital or other environment that needs to be hygienic and safe for employees and visitors. The use of antimicrobial material like silver is known to reduce the level of harmful microbes. Adding materials like silver to high-touch surfaces like handles and shared devices can help prevent the spread of bacteria and reduce the rate of hospital-acquired infections (Salto Systems n.d.).

Credential Authentication and Functionality

When an individual's credentials are presented and verified, the system grants them access. Each access control system uses different methods to authenticate users. According to Stalling and Brown (2008), there are four general means of authenticating a user's identity:

- **Something the individual knows**: Examples include a password, a personal identification number (PIN), or answers to a prearranged set of questions.
- **Something the individual possesses**: Examples include electronic keycards, smart cards, and physical keys. This type of authentication is referred to as "token."
- **Something the individual is (static biometrics)**: Examples include recognition by fingerprint, retina, and face.
- **Something the individual does (dynamic biometrics)**: Examples include recognition by voice pattern, handwriting characteristics, and typing rhythm (p. 75).

An example of a secure credential is a combination of a proximity card (*something the individual possesses)* and a PIN (*something the individual knows)*. This is an illustration of a 2FA or two-factor authentication.

Before the user's credentials can be presented and verified, the administrator must enroll the user into the system. First, administrator enters the user's information into a database table. The database contains fields such as identification number, name, title, department, street address, city, and telephone number. Most access control software allows customization, for example, adding more fields, according to a company's requirements and protocols.

Different users require different levels of access. After enrollment, the administrator assigns access points or zones (a cluster of access points) and/or specific time restrictions, if required by the institution's security policy. If the system uses a keypad with a PIN, the system conceals the number from the administrator during the enrollment process. Furthermore, if the access control system uses biometric readers, each person's biometric data is scanned, analyzed, and stored in an encrypted format in a secure database.

After the enrollment process, the user may attempt to access the system. The user presents a credential in the form of a smart card, biometric, or PIN to a digital reader. The reader then forwards the credential to a control panel or controller. The controller receives the request to unlock the relay (the electromagnetic apparatus used as a remote operating switch), which is connected to an access point (door, gate, etc.). Finally, the controller (communicating wirelessly or through a local area network (LAN)) accesses the software. Using distributed intelligence, the controller is fully functional even when the software is not communicating with the hardware, enabling the system to work continuously. It is the software that accesses the server and decides whether to unlock the door. The system uses a web application that contains stored data on a remote data server and utilizes a web browser as a client. If the credentials offered match the name in the database, the controller opens the door. If there is no match, permission is denied, and the reader indicates this with a flashing red light-emitting diode (LED). If access is permitted, the LED light flashes green. The following figure displays a typical access control setup with its components.

The credential transaction shown in the above figure is the simplest form of *authentication* method, single-factor authentication (SFA). The system recognizes that the user requesting access employs only one credentialing method, for example, a username and a password or an access card presented to the reader. For improved security, a two-factor authentication (2FA) or a multifactor authentication (MFA) is employed (NIST n.d.-a). The Paul Sarbanes and Michael Oxley act (Sarbanes-Oxley Act of 2002) and HIPAA require that institutions establish strong internal controls to mitigate risks and protect data centers from data breaches (Gordon et al. 2005; Srinivasan 2014). The 2FA and MFA methods use more than one factor to confirm the identity of a user, thereby improving security. An example of the 2FA method could be an access card as the first credential and a secret PIN or biometric identification as the second credential.

Access Control System Topology and Standards

Access control systems are classified as stand-alone, server-based, or utilizing distributed intelligence. Stand-alone access control provides access in situations with minimal problems, like lack of visibility and control of database activity, lack of remote managing and control of users, limited user capacity, and lack of software and/or no audit trail. Additionally, the user database and enrollment information are stored in the reader. This topology is often chosen for controlling apartment or private office doors that do not require management, have many users, and do not require constant monitoring.

Server-based access control is a client-based system which accesses a database and a server. All data concerning the access control system (enrollment user data, authentication requests, access to history and real-time audit trail) reside on the server. When the reader sends an access request to the controller, the controller then sends the request for authentication to the server; finally, the server's database grants or denies the request.

Distributed intelligence access control allows real-time data exchange between locks and credentials (cards, fobs, etc.). The administrator accesses the software to affirm credentials, access as well as integrate locks, and update, restrict access, or delete a user remotely. Additionally, the administrator can view supporting information in real time, such as audit trails, display times, date, and information about user access or denial. Most modern server-based systems incorporate this technology into wireless locks and credentials like RFID cards and mobile apps. Server-based and distributed intelligence access control systems are usually more expensive and require certified license contractors for installation. Corporations with thousands of users and hundreds of doors and exits purchase these systems. Distributed intelligence access controls are found in high-end apartment buildings and smart houses as well.

Access control systems use the Wiegand electrical data interface protocol for communication among the controller, reader, and credential and refer to this as data encoding among the devices (HID n.d.). More specifically, the Wiegand protocol connects peripheral devices (biometric reader, card) with the access control system. The interface contains three connecting wires: the ground wire and two other data transmissions, identified as Data low/DATA 0 and Data high/DATA 1 (HID n.d.). Contactless smart cards follow ISO/IEC 14443, ISO/IEC 15693, or ISO/IEC 18000 standards, developed by the International Organization for Standardization (ISO n.d.-b) and the International Electrotechnical Commission (IEC n.d.). In addition to the above installation and encoding standards, access control systems are governed by the National Fire Protection Association's (NFPA) regulation 101T Life Safety Code (NFPA n.d.) and the International Building Code (ISO n.d.-a) that specifies the range of use of electromagnetic locks. Finally, for access control systems used at federal facilities, the NIST has developed best practice guidelines for integrating credentials with the physical access control systems (PACS) (NIST n.d.-b).

Security Concerns and Risks

Any software that resides on a network and works alongside a variety of IP-based devices (readers, locks, and controllers) is vulnerable to a variety of attacks. By compromising an access control system, a hacker would not only have access to its database, but could control all access points. The hacker could threaten to leak users' sensitive information, delete access data from users' profiles, and open every door or gate connected to the system unless the institution pays ransom. Many companies that are turning to IP-based access control systems lack awareness and understanding of the security vulnerabilities that can lead to an attack. Another problem is the lack of communication and collaboration among installers, system administrators, and the IT security of the organization. As a result, IT security can overlook issues such as insecure software, firmware, installation of the readers, controllers and wireless locks, unprotected mobile app interfaces, insecure web interfaces, and lack of transport encryption. They may choose to favor convenience over security by simplifying usernames and passwords.

Another issue is that some software manufacturers do not provide follow-up with IT security after installation. Furthermore, some components (readers, locks) come from third-party vendors and run on outdated software/firmware. Hypothetically, an attacker could exploit all the above vulnerabilities to gain access to organization's networks. Hacking techniques include packet sniffers (Wireshark), where a hacker first captures and then analyzes data packets that can be used to obtain information like passwords, and the man-in-the-middle (MITM) attack, where the hacker eavesdrops on the communication between two targets using a separate computer that accepts traffic from each one (Gibson 2009). Security attacks are increasing in quantity and severity every year, and will not lessen, especially when hackers know that organizations will meet their ransom demands.

Conclusion

Physical access control technology has grown tremendously in recent years and is changing how we secure our sites. Wireless solutions, used with a variety of credentials, can secure many things besides doors and gates. Smart homes integrate access controls, a variety of credentials, and a security system, along with closed-circuit cameras and lighting and sound systems, under a single control panel that can be accessed from anywhere in the world. Those using wireless solutions can expect an increase in IT vulnerabilities and data breaches. In the corporate environment, physical access controls, used with fire alarm systems, are becoming critical investments for every organization.

The choice of an access control system should be treated as a long-term capital investment. According to the Technology Acceptance Model (TAM) (Davis 1986, 1989), two factors influence technology adoption, the technology's perceived usefulness and perceived ease of use. Thus, an access control system should be both easy to use and should have the ability to transform the organization. The system must have distributed intelligence and the ability to integrate with other systems, such as closed-circuit cameras, alarms, and fire systems. The system must follow accepted fire and life-safety codes. In addition, the system should be able to expand and handle additional users, devices, and locations within one application. In the age of mobility, users should be able to gain access to and monitor the system using credential and monitoring apps on their mobile devices.

Credentials should offer convenience and ease of use and of course should be cost-effective. Biometric authentication credentials must be evaluated based on accuracy factors, such as FAR, FRR, and identification rate. In some cases, a mobile phone app using Bluetooth or near-field communication (NFC) may be used as a credential for communicating between the mobile phone and the lock. Furthermore, from a security perspective, the system should be able to accept smart credentials like encrypted RFID card technology and biometric readers. Finally, one of the most important security factors is that the manufacturers must provide critical software updates, including security and firmware updates, on a regular basis, in conjunction with the IT department of the organization. Communication between the vendor, manufacturer, and IT department and systematic training of administrators are critical for the success of the system. Any system cannot survive and be effective unless the human element is handled successfully. In today's digital world of increasing cybersecurity awareness, it is important to combine both *physical and logical access controls* in the effort to restrict, analyze, and protect access to network data and physical locations.

Physical security · Detection · Delay · Response · Design

Definition

Physical security methods and practices are those systematic plans and actual uses of countermeasures applied to prevent unauthorized access to, and protect against malicious acts upon, critical assets.

Introduction

Physical security – despite the simplistic refrain that all it consists of is "gates, guards, and guns" – is not a "one-size-fits-all" enterprise. Rather, it consists of the use of active and passive measures to protect critical assets from adversary or criminal activities by preventing unauthorized access to critical assets – be they personnel, buildings, geographic areas, or equipment (see ▶ "Insider Threat" for further discussion). According to the US Department of Defense, physical security is defined as "That part of security concerned with physical measures designed to safeguard personnel; to prevent unauthorized access to equipment, installations, material, and documents; and to safeguard them against espionage, sabotage, damage, and theft" (2016, p. 185). In addition,

SAND9629J Sandia National Laboratories is a multimission laboratory managed and operated by National Technology and Engineering Solutions of Sandia, LLC., a wholly owned subsidiary of Honeywell International, Inc., for the US Department of Energy's National Nuclear Security Administration under contract DE-NA-0003525.

physical security seeks the "protection of Federal employees and private citizens who within and visit U.S. government-owned or leased facilities" (Interagency Security Council 2015, p. iii).

After describing high-level physical security goals, the rest of this entry describes how two mechanisms can support the completion of such goals for critical assets. The first consists of *physical security methods*, or the systematic planning related to physical security countermeasures implemented for protecting critical assets (e.g., systems-engineering design frameworks). The second encompasses *physical security practices*, or how physical security countermeasures are used to protect critical assets (e.g., facility-specific access control procedures).

The Goals of Physical Security

To evaluate the effectiveness of related methods and practices, it is necessary to understand the goals of physical security. Physical security can best be measured by the ability of *countermeasures* –technologies, procedures, and individuals – to interact in support of all efforts to identify, slow, and neutralize any adversary or criminal action against critical assets (Garcia 2008; Interagency Security Council 2015). More simply put, the "theory and application of physical [security], include the functions of deterrence, *detection*, *delay*, and *response*" (Interagency Security Council 2015, p. 19).

Detection, as a physical security goal, relates to all countermeasures that communicate the occurrences of an adversary or criminal activity against an asset is occurring. Examples include guard patrols observing an individual climbing a perimeter fence or a motion sensor indicating movement inside a locked vault. The detection goal includes the process by which observations of undesired actions (e.g., surveillance and monitoring) are analyzed (e.g., detection and assessment) and lead to decisions to initiate additional protection actions. When concentrated farther away from critical assets, detection countermeasures are more effective and efficient because they provide additional time for more accurate assessment and for supplementary protection actions to be taken. Detection effectiveness is generally described as the likelihood that the selected collection of related countermeasures are able to adequately identify the presence of adversary or criminal activities threatening critical assets. (For additional discussion on related topics, see ▶ "Intrusion Detection Systems," ▶ "Physical Security: Interior Applications," or ▶ "Physical Security: Video Surveillance, Equipment, and Training.")

Delay, as a physical security goal, includes countermeasures employed to increase the physical resources, intellectual capabilities, and time necessary for an adversary or criminal action to be successful. Common examples of delay countermeasures include cement bollards to prevent vehicle access or enhanced locking mechanisms on entrances to sensitive buildings. Countermeasures selected and implemented to support delay goals seek to insert additional time into adversary or criminal activities for other protection actions to be successfully deployed. Delay-related countermeasures are most effective and efficient when they occur after detection and are concentrated closer to critical assets. (Perhaps the quintessential example of the "delay after detection" mantra is illustrated in a scene from the 1994 film *The Shawshank Redemption*. In the film, Andy Dufresne spent years slowly chipping away at his cement-walled prison cell. He was able to eventually dig a hole large enough to facilitate his escape – completely unbeknownst to the prison guards or warden. In this example, even the delay of multiple-foot-thick prison cell walls are negated because there was no forewarning – or detection – of the malicious act.) The ability to achieve delay-related goals is described as the additional time provided by extra physical, temporal, or cognitive burdens placed on adversary or criminal activities against critical assets.

Response, as a physical security goal, incorporates countermeasures for neutralizing adversary or criminal activities against critical assets by killing, capturing, or causing them to flee. Examples include using onsite guard personnel to cordon off a specific area to contain the perpetrators or the arrival of an offsite, armed

local law enforcement agency. Countermeasures supporting response goals can include providing improved equipment, requiring advanced tactical training, enhancing communications, or moving forces closer to critical assets. Timely and appropriate response, in general, is most effective and efficient when coordinated with early detection and sufficient delay by other physical security countermeasures. Response effectiveness is commonly described as the speed and efficiency with which appropriate response personnel – most often agencies with national or local authority to carry weapons – are able to arrive and neutralize adversary or criminal activities against critical assets. (For additional discussion on related topics, see ▶"Security Guards: Academic and Training Programs" or ▶"Security Guards: Authority and Power.")

Taken together, these physical security goals aim to prevent interruptions to the benefits provided by critical assets – arguing that there is an inherent need for alignment between physical security goals and desired asset operations. Therefore, the level to which countermeasures independently and interdependently operate to achieve high-level physical security goals *within* the context of normal facility operations will determine the overall effectiveness of being able to protect critical assets. According to the US Interagency Security Council (ISC), it is important to "articulate how a holistic and comprehensive physical security program contributes to the success of the agency and its mission" (Interagency Security Council 2015, p. 20). Achieving physical security goals can be most efficiently and effectively achieved by leveraging insights from well-known physical security methods and practices.

Overview of Physical Security Methods

Successfully detecting, delaying, and responding to adversary or criminal activities to protect critical assets require strategic thought, tactical understanding, and rigorous evaluation. In response, physical security *methods* can be defined as systematic planning processes to identify, select, and arrange physical security countermeasures to protect critical assets from threats. Navigating such influences as normal asset operations, natural terrain, and architectural designs on physical security performance requires an emphasis on balance identifying, selecting, and arranging countermeasures. While various methods exist for identifying, selecting, and arranging physical security countermeasures to protect critical assets, this entry uses two examples to crystallize this concept. The first is the *design evaluation and process outline*, which was created at Sandia National Laboratories for the protection of various US Department of Defense and US Department of Energy critical assets. The second is *crime prevention through environmental design*, which evolved from the "defensible space" concept that emerged from the union of criminology and architecture domains in the 1970s (Ray 1971).

The Design Evaluation Process Outline (DEPO) builds generic systems engineering concepts for its systematic planning for physical security. DEPO is popularly considered the current standard for security analysis at nuclear facilities (Garcia 2008). The DEPO methodology consists of the following key steps (Garcia 2008):

- Characterize the facility (e.g., *defining its mission*)
- Identify the undesired events and critical assets (e.g., *identifying assets as theft or sabotage targets*)
- Determine potential consequences of undesired events (e.g., *defining facility damage, or health effects)*
- Define threats to the facility (e.g., *identifying anticipated adversary capabilities*)
- Analyze security system effectiveness (e.g., *evaluating performance of physical security countermeasures*)
- Estimate the risk (e.g., *determining how well the physical security countermeasures mitigate adversary activities)*
- Compare this risk to the *acceptable* risk level from the competent authority and:
  - If sufficient, complete the (re)design of physical security countermeasures.
  - If insufficient, suggest (and re-evaluate) physical security countermeasure upgrades.

The DEPO method argues that the "detect, delay, and respond" paradigm fully describes the necessary functions of strong physical security (Garcia 2008). As a physical security method, DEPO seeks to between the accepted level of risk (e.g., the likelihood of successful adversary or criminal action) and physical security upgrade impact to facility budget and operations. To do so, DEPO shares a philosophical foundation with popular probabilistic risk assessment approaches to safety and arranges countermeasures to make adversary tasks more complex and take longer to complete. According to DEPO, extending the adversary or criminal timeline improves the ability of countermeasures to achieve physical security-related goals.

To this end, DEPO describes how well an arranged collection of physical security countermeasures to achieve a defined ability of defeating a specific adversary along a specific attack path. More specifically, this method describes a conditional probability that adversary or criminal activities will be interrupted in time for them to be neutralized for how well detection and delay goals are achieved. Similarly, DEPO describes a conditional probability that, once interrupted, adversary or criminal activities are neutralized for how delay and response goals are achieved. Ultimately, the DEPO method produces an overall description – called the system effectiveness – of the ability of a given collection of physical security countermeasures to achieve detection, delay, and response goals to protect critical assets against malicious acts. (DEPO uses the formula $R = P_A * (1-P_E) * C$ to determine system effectiveness, where P_A is the assumed probability of attack, C is a quantitative approximation of qualitative consequence descriptions, and P_E is the physical security system effectiveness. To mitigate the difficulty of predicting adversary actions (P_A), DEPO best practices set $P_A = 1$ to simplify the equation to $R_C = (1-P_E) * C$. With physical security now described as a conditional probability, P_E is defined as the product of the probability of interruption (P_I) and the probability of neutralization (P_N), where P_I and P_N are nested, conditional probabilities related to physical security countermeasure performance.)

A second example of a physical security method is Crime Prevention through Environmental Design (CPTED). This method is based on the argument that urban form – including landscapes, buildings, and traffic flow patterns – can be used to reduce criminal activity. This multidisciplinary approach leverages concepts from social, behavioral, psychological, and biological explanations for what causes criminal and malicious behavior. More specifically, CPTED is:

> A process for analyzing and assessing crime risks in order to guide the design, management, and use of the built environment (and products) to reduce crime and the fear of crime and to promote public health, sustainability and quality of life. (Cozens and Love 2015, p. 14)

CPTED, ideally, is implemented during design phases, because they offer the most flexibility and control over potential changes in the environment. Cozens & Love (2015) summarize this method in terms of seven physical and four social strategies. These physical strategies include creating a sense of ownership to protect an asset (e.g., "territorial reinforcement"); observing various activities in an area around an asset (e.g., "surveillance"); maintaining appearance to transmit positive signals about an asset (e.g., "image"); limiting entrance to, or contact with, an asset (e.g., "access control"); promoting high levels of desired activities around assets (e.g., "legitimate activity support"); increasing the physical difficulty of accessing an asset (e.g., "target hardening"); and using the influence adjacent "safe zones" to protect assets (e.g., "geographical juxtaposition"). Similarly, the four social strategies, according to Cozens & Love (2015), include building a mutual respect among members in a local community (e.g., "social cohesion"), coordinating activities among members in a local community (e.g., "community connectivity"), sharing a sense of place between members of a local community (e.g., "community culture"), and understanding the finite ability to support certain community activities (e.g., "threshold capacity"). CPTED has a long history of being used as a method to reduce crime in community spaces (Cozens and Love 2015) – which provides examples of how its use for systematic planning helps

achieve physical security goals. For example, CPTED's argument that revitalizing dilapidated portions of neighborhoods will eliminate opportunities to conceal criminal activities is similar to the physical security goal of detection. Similarly by restricting access, delay is demonstrated in CPTED-based redesigns of walking paths to limit entranceways into public space. The social strategies listed above also serve to better incorporate relevant law enforcement agencies into CPTED-based plans which results in increased familiarity and trust with the community. This can cause more effective and more efficient prevention of crime by these law enforcement agencies and directly serves the response physical security goal. As a method, CPTED "continues to represent an attractive option for individuals, communities, local, state and national governments and international organizations alike" (Cozens and Love 2015, p. 14) for leveraging to achieve physical security goals for critical assets.

Additional physical security methods also exist. One other popular method, known as "defense-in-depth," argues for using combinations of physical security countermeasures (each considered insufficient to meet physical security goals on their own) in concentric layers to enhance physical security performance. For example, using a chain-link fence and ring of tall shrubbery around a public space combines the robustness of the former with the opacity of the latter to enhance the overall physical security of the space. The concept of a "graded approach" – which argues for appropriately matching selected and arranged physical security countermeasures to facility operations, anticipated threats, and potential consequences – is another systematic planning process for physical security. Consider, for example, the countermeasures employed to protect a remote power substation in the rural USA. Midwest will look different than those for a nuclear power plant near a metropolitan area for the same anticipated threat because of the differences in operations and potential consequences. Despite the common goals of detecting, delaying, and responding to adversary or criminal activities to protect critical assets, physical security methods provide systematic planning processes to avoid a "one-size-fits-all" physical security mentality.

Actual Application(s) to Protect Assets from Threats: Physical Security Practices

In physical security, systematic planning should be augmented by a deeper understanding of (and expectations for) the patterns that describe regular application of physical security countermeasures. In other words, where methods illustrate systematic planning processes for physical security countermeasures (e.g., actions taken during the *design* of physical security), practices describe how such countermeasures are routinely *used*. Physical security *practices*, then, can be defined as the behavioral patterns of how individuals interact with physical security countermeasures to achieve asset protection goals. Therefore, the ability to achieve physical security goals is enhanced with a deeper understanding of such behavioral patterns, and, while many exist, two are described in more detail to illustrate the importance of this concept.

Successful physical security is predicated on the having an accurate understanding of the current conditions impacting countermeasure performance and the asset they are intended to protect. *Surveillance* is a key physical security practice that relates to countermeasures are used to make observations that inform this understanding of current conditions influencing asset protection. Traditionally, surveillance relates to targeted, close observation of suspicious (or, expected to be suspicious) activities – surveilling an employee suspected of tampering with a bank vault, for example. There are different kinds of observations, however, that can inform knowledge of the current conditions impacting countermeasures. Monitoring, for example, describes efforts for broad observations of critical assets at regular time intervals, often as a quality control mechanism. Consider cameras aimed at the entrance door to a bank, for example. Another type – assessment – describes the ability to distinguish between non-malicious and malicious intent for unexpected or unanticipated observations. Ultimately, assessments aim to identify whether the

observation was a tumbleweed blowing into the bank lobby or an adversary or criminal activity.

As a physical security practice, surveillance supports both DEPO- and CPTED-based countermeasure designs to achieve high-level physical security goals. In DEPO, various technical- and human-based countermeasures are identified and implemented to improve the observation and communication of unexpected activities to support the method's emphasis on assessed detection (Garcia 2008). Common examples include roving guard patrols along a facility's perimeter and closed-circuit television (CCTV) systems. Similarly, CPTED argues that the ability (and the *perceived* ability) for regular observations of activities in public spaces deters criminal acts for fear of exposure and attribution. CPTED-specific examples include street design (e.g., one-way traffic flows), the location of building windows (e.g., some should face the back alley), and CCTV (Cozens and Love 2015). Whether performing under the specific parameters of surveillance, monitoring, or assessment, physical security is enhanced when countermeasures improve the quantity and quality of observations on conditions related to protecting assets.

In addition to having early warnings of potentially adversary or criminal activities, physical security is also enhanced by efforts to purposefully restrict proximity to (or contact with) critical assets. This physical security practice distinguishes between who does (and who does not) have authority to access a critical asset. Called *access control*, this practice includes behavioral patterns that use countermeasures to limit the ability for close proximity or contact with critical assets. Related practices include more formal efforts like background investigations commonly used for US government jobs requiring a national security clearance and informal mechanisms like neighbor-based identification of "strangers" in the community. Access control practices also include discriminating based on the type of access allowed to support achieving physical security goals. For example, access to a bank's vault can range from bank customers being escorted to their safety deposit boxes to bank employers entering the vault unescorted during business hours to bank managers having the codes to open the vault during nonbusiness hours. Asset protection, then, can be enhanced by practices that restrict the number of people or the type of proximity to assets that are permitted.

Access control practices, like surveillance, supports DEPO- and CPTED-based countermeasures to help achieve high-level physical security goals. Related practices include both technological and procedural mechanisms to (at best) eliminate or (at worst) reduce unauthorized access to protected assets. Common DEPO-based applications of access control include the use of identification badges – from simple visual inspection to electronic examination to biometric verification. Likewise, one of the key CPTED strategies centers on access control, more specifically emphasizing both natural and man-made uses of "spatial definition to deny access to potential targets" (Cozens and Love 2015, p. 5). Using landscape features like steep terrain or creeks to locate entranceways are traditional CPTED-related approaches to access control, but more recent practices include using mechanical locks and cages to deny unauthorized proximity to assets. In both DEPO- and CPTED-related instantiations, access control practices support achieving high-level delay goals. When used to support surveillance efforts (e.g., alerting when an employee suspected of malicious intent attempts access to an asset), access control can also help achieve detection goals. These practices can also support high-level physical security response goals, particularly when utilized in a forensic or investigatory role.

While surveillance and access control were highlighted in this entry they are not the only physical security practices to consider in achieving physical security goals. Another visible physical security practice is employing dedicated, on-site guard personnel. Such personnel can range from contracted personnel who focus on small theft prevention (as in many US retail stores) to (un)armed individuals who focus on slowing criminal activities (as in many US commercial banks) to armed personnel with paramilitary training (as in many US nuclear power plants). Another popular physical security

practice relates to the use of protection zones, where different levels of countermeasures are located to protect different types of assets. Most clearly related to the aforementioned "defense-in-depth" physical security method, this practice places more valuable assets in zones that require more robust countermeasures, with the tendency of placing the highest value assets in the center of a concentric set of protection zones. An example of clear protection zones are those around nuclear power plants, but similar practices can be seen in more common organizations like airports where increasingly robust countermeasures protect access to the terminal(s), aircraft, tarmac, and air traffic control towers. Taken together, this section demonstrates the important role of how regular patterns of using countermeasures support systematic planning processes to achieve physical security goals to protect critical assets.

Conclusions

Physical security methods and practices must continually adapt to changing and expanding challenges into opportunities for better critical asset protection. Consider the natural tension between physical security countermeasures and the operational focus of critical infrastructure, like the difficulty in balancing between the resources spent on attempting to detect weapons entering an airport and the need for airports to process thousands of people an hour. Here, coupling a focus on preventing interruptions to normal operations with detection, delay, and response goals provides the opportunity to develop new systematic planning processes and patterns of behaviors to protect critical assets. Another challenge is confusing "threat" (or, those aspects of physical security that *cannot* be controlled) and "vulnerability" (or, those aspects of physical security that *can* be controlled). Threats to physical security can either be natural (e.g., floods, fires, hurricanes) or intentional (e.g., terrorist or criminal acts), whereas vulnerabilities are faults within countermeasures that can be addressed (and resolved) with physical security methods and practices. Further, new and evolving threats should be used as drivers for innovation in physical security methods and practices. One last challenge is the increasing digitization of physical security countermeasures (e.g., controllers of physical countermeasures or networked countermeasure system designs). This, in turn, provides the opportunity to better incorporate key cyber security and information protection strategies into physical security methods and practices. Ultimately, combining and leveraging the benefits of well-known – and developing new, innovative – physical security methods and practices can help overcome these challenges to ensure that critical infrastructure assets are protected and able to support their role in society.

Definition

The use of video surveillance for physical security refers to closed circuit television (CCTV). CCTV is used as a generic term to describe one or more video cameras that are connected via a closed system to a central television monitor or recording device (Ratcliffe 2011). The terms video surveillance and CCTV are used interchangeably in this entry.

Introduction

Video surveillance systems are commonly employed as a physical security measure in many western countries. The number of cameras being used in the United Kingdom – an early leader in embracing the use of CCTV, through the support of the Home Office (Armitage 2002) – is estimated to be between two and six million (British Security Industry Association 2013; Gerrard and Thompson 2011; McCahill and Norris 2002). Almost half of all US police departments, and as high as 90% for large departments, use video cameras for surveillance of public areas (Reaves 2015). Several large US cities have invested heavily in video surveillance; for example, Chicago now has more than 30,000 cameras in public areas (Williams 2018). Australia also has a significant investment in public space CCTV by local councils. Between 2005 and 2014, there has been a sixfold increase in the proportion of councils responsible for the installation and monitoring of public space video surveillance systems that use federal, state, and territory government funds (Hulme et al. 2015). Meanwhile, the largest growth in CCTV has been observed in Asia. Industry estimates have placed the number of cameras in China at approaching 200 million, with plans to grow this number significantly in the short term (Mitchell and Diamond 2018) as part of a larger surveillance network (Liang et al. 2018).

Evidence supports the finding that CCTV makes an important contribution to public safety and helps guide decisions by private and public security managers about when, where, and how CCTV is used. This entry begins by exploring the different features of video surveillance systems, followed by a description of how CCTV is meant to enhance public safety. The data evaluating the effectiveness of CCTV is briefly reviewed, including support for features that seem to be key to security management. Lessons for the effective use of CCTV as a physical security measure, including equipment and training, are then outlined.

Characteristics of Video Surveillance Systems

The size of the global video surveillance market has been estimated at over $30 billion (BIS Research 2018). Video surveillance systems

comprise several main elements, including cameras and lenses, monitors, recording devices and video storage, the hardware connecting each of these, and relevant supporting infrastructure. However, the configuration of video surveillance systems can vary widely from a single camera to many thousands of connected cameras or from simple inexpensive home installations to large-scale multi-million-dollar public space networks. In addition to private residences, CCTV systems are utilized in a range of settings where there may be security risks, including retail and commercial premises, financial institutions, public transport, car parks, city centers, and entertainment precincts and venues.

Cameras may be stationary, with a fixed field of vision, or move according to a pre-programmed pattern of movement, while pan, tilt, and zoom (PTZ) cameras allow for operators to control the movement of cameras and focus on targets of interest. PTZ cameras have become increasingly common, particularly in those systems that are monitored by camera operators, while pre-programmed and stationary cameras are often criticized for failing to capture important moments or features of an incident (La Vigne et al. 2011). There has also been an increase in the use of mobile cameras, which allow video surveillance to be deployed in known hot spots.

Contemporary video cameras use digital technology, although they may be connected to existing analogue cameras, particularly in those situations where an existing network is being expanded or upgraded. Digital cameras offer significant advantages over analogue cameras but, even then, can vary in terms of image capture and resolution. This is influenced by a wide range of factors, including the type and quality of the camera and camera lens, the lighting that is available (and whether the camera adjusts to day- or nighttime and is able to perform well in low-light situations), the type and level of digital video compression for image transmission and storage, and the resolution, scaling, and capabilities of the display device. Fundamental to the performance of a video surveillance system in terms of capturing a high-quality image are the type and features of the camera lens; there is little capacity to compensate for a poor-quality lens with other components of the system.

Cameras may be connected via cabling, via wireless connectivity, and increasingly, via Internet protocol networks. Internet protocol cameras have grown in popularity, due to their capacity to provide high-quality image resolution at a comparatively low cost. Cameras are usually connected to a central monitor, or bank of screens, while digital technology allows for footage from multiple cameras to be recorded simultaneously. Footage is usually recorded on digital video recorders or network video recorders, the size of which will be influenced by the quality of video recorded, as well as the length of time (i.e., how many days) the footage needs to be retained before being recorded over. Many systems still rely on write-once, read-many media – such as CDs and DVDs – for video storage, but there is a shift toward secure network storage, particularly for larger systems. In avoiding the need to handle storage disks, which can be cumbersome, network storage is more readily scalable as a network or storage requirements grow (Space and Naval Warfare Systems Center Atlantic 2013).

Camera systems may be live monitored, passively monitored, or unmonitored. Monitoring requirements will dictate the number and type of monitors (e.g., display resolution, size, layout) that are used to view images. The major advantage of monitored systems is the ability to detect incidents as they occur and to deploy security or police shortly thereafter. This has significant resource implications, including to establish control rooms and provide ongoing staffing, and requires effective communication between camera operators and frontline responders. Research suggests that most systems are not monitored and that the proportion of public space systems monitored has fallen as the number of systems has grown (Hulme et al. 2015), and most criminal incidents that occur in locations with video surveillance are not detected by CCTV operators (Piza et al. 2014b). However, this varies by context, with larger public infrastructure systems – which might be supported by dedicated security or direct communication with police – more likely to include a monitoring

capability (e.g., public transport surveillance networks; see Ashby 2017; Morgan and Coughlan 2018). Footage that is not monitored may still be recorded – and stored for a minimum length of time – which allows investigators and other users to access footage at a later date. However, not all operators routinely record footage, usually because of resource implications.

Importantly, video surveillance systems are rarely used in isolation of other public safety measures. Instead, they are used in combination with access control measures, street lighting, crime prevention through environmental design, and the deployment of security guards. These other forms of public area surveillance are effective crime prevention measures themselves (Welsh et al. 2015). Similarly, police use CCTV alongside a raft of other technology, while video surveillance in law enforcement settings also includes body-worn cameras, automatic number plate recognition systems, and facial recognition. In fact, most significant advances in contemporary policing revolve around the introduction of new technologies for law enforcement. Although this entry focuses on video surveillance, it must be understood that this is often implemented as part of a larger strategy.

Potential for CCTV to Reduce Crime and Improve Public Safety

According to Gill and Spriggs (2005), there are several possible mechanisms through which video surveillance may help to reduce crime and improve public safety. Although there has been little attempt to empirically test these mechanisms, they are important because the way CCTV works has implications for how systems are designed and implemented (see ▶ "Physical Security: Best Practices" and ▶ "Physical Security: Video Surveillance, Equipment, and Training" in this encyclopedia). These mechanisms are also helpful in interpreting the research findings that follow.

The most obvious of these mechanisms, and the mechanism that is most commonly assumed, is general deterrence. Potential offenders may be deterred by the presence of video surveillance because it increases their perceived risk of getting caught. This assumes that offenders are aware that cameras are installed in the area – which requires cameras and signage be visible – and believe they are being monitored or that footage is used to identify offenders and that the risk of being apprehended outweighs the potential rewards associated with committing crimes in areas with surveillance cameras installed.

Several other mechanisms are possible. These include that video surveillance increases the actual likelihood of an offender being apprehended and processed through the criminal justice system, which reduces their likelihood of repeat offending through incapacitation or specific deterrence. Given the high proportion of offenses committed by repeat offenders, often against the same targets, this seems plausible (Grove and Farrell 2012), particularly in high-crime areas. In areas where quality CCTV footage is collected and stored, and partnership arrangements between CCTV operators and police exist to facilitate footage retrieval, the ability to identify and prosecute offenders should be enhanced. Video surveillance systems that are monitored may support the rapid deployment of police and security staff to incidents when they occur, or when individuals are acting suspiciously, which can interrupt offenders and prevent crime from occurring or escalating.

Other mechanisms may be more indirect. Video surveillance is often installed with the goal (usually alongside crime prevention) of improving perceptions of safety because of how it might influence people's perception of the space. The presence of video surveillance devices may signal to potential users of public space that the area is safe, making them less likely to worry about security risks and more likely to visit, and the increased presence may result in increased informal or natural surveillance from people who may act as capable guardians, a known deterrent to offenders. Conversely, the presence of visible CCTV may indicate to people using the space that there is a security risk, encouraging those who are more security-minded to take additional precautions.

Finally, video surveillance may also have potential negative consequences, which could lead to an increase in crime. It is possible that recorded crime will increase, not because of actual changes in crime, but because CCTV increases the number of crimes that are detected by police (Winge and Knutsson 2003). Another possibility is that police, security personnel, and members of the community become less vigilant in the presence of video surveillance, because they believe would-be offenders will be deterred or that, if something were to happen, those monitoring the cameras will respond quickly to intervene. It is also possible that CCTV will lead to a decrease in natural surveillance, because people who do not like the idea of being captured on camera avoid the area. Whether the concerns raised in relation to privacy implications of public space surveillance actually lead to changes in behavior in public spaces has not been subjected to any empirical analysis.

There are other uses for video surveillance, including monitoring of industrial operations, traffic monitoring, counter terrorism, and emergency management, which are important but outside the scope of this entry. In summary, video surveillance has the potential to deliver several benefits relating to physical security in public spaces, including reduce crime, improved community safety, more responsive policing, and better investigative outcomes. This entry now turns to discussing the evidence regarding the efficacy of video surveillance in each of these domains.

Effectiveness of CCTV

There is now a very large body of high-quality research that has evaluated the effectiveness of video surveillance, more so than just about any other situational crime prevention measure. Most of this research has focused on the crime prevention effects of CCTV, particularly in the United States and United Kingdom and increasingly other parts of Europe. A recent systematic review of 40 years of evaluations provides the best of evidence of the effectiveness of CCTV as a crime prevention measure, as well as the circumstances under which it works most effectively (Piza et al. 2019). To be included in this review, studies must have measured crime before and after the installation of CCTV (allowing analysis of crime trends), including in the area with cameras and a similar location without cameras installed. This qualification allowed researchers to determine whether any changes in crime could be attributed to the intervention, in this case CCTV, or whether it reflected broader trends or was the result of some other cause.

Overall, Piza et al. (2019) analyzed 80 high-quality studies and found CCTV was associated with a modest, but significant, reduction in crime. Consistent with earlier reviews (e.g., Welsh and Farrington 2009), they found that CCTV was most effective in reducing crime in car parks, primarily thefts from motor vehicles. However, there was also evidence of a positive impact in residential settings. Drug crime, namely, drug selling, had the largest overall effect size – albeit in a smaller number of studies – suggesting drug sellers may be deterred by the presence of security cameras. CCTV was less effective in other settings, such as city centers, and had no impact on violent crime. This is most likely because of the impulsive nature of violence occurring in public spaces (Felson and Massoglia 2012), as well as the fact that many offenders are likely to be affected by alcohol and drugs (Ratcliffe 2011). These factors together likely undermined the deterrent effects of visible security measures, such as CCTV cameras. In circumstances in which crime had been reduced, there was little evidence of displacement, meaning that the crime problem had not simply moved somewhere else, a finding which is consistent with the broader literature on situational crime prevention (Johnson et al. 2014).

There is much less evidence that video surveillance has a positive effect on perceptions of safety. Lorenc et al. (2013) conducted a systematic review of environmental responses to fear of crime, finding limited evidence in support of CCTV. Some studies have produced no effect or small positive effects, whereas others have shown that the installation of CCTV made people feel unsafe. One explanation for these

mixed results is that other factors – such as prior victimization – significantly influence how safe people feel in public spaces despite the presence or absence of physical security measures, such as video surveillance.

While there is an abundance of research into the crime prevention effects of CCTV, the main reason police invest in video surveillance is offender detection and apprehension (Ratcliffe 2011). A small number of studies have shown that CCTV can have a modest effect on the deployment of police. In their Australian study, Wells et al. (2006) conducted 100 h of observation in a CCTV control room, where 181 incidents were viewed by camera operators, resulting in 51 arrests; however, only seven of these arrests were the direct result of the camera network. In another study, Piza et al. (2014b) found that incidents detected using monitored CCTV were more likely than calls for service to result in an offender being apprehended. But this effect was atypical and became even less common as the system increased in size because of the concomitant strain on resources to monitor the footage from multiple monitors actively.

Other studies have shown that CCTV is often used by police to investigate crime (Ashby 2017; Dowling et al. 2019; La Vigne et al. 2011; Levesley and Martin 2005; Morgan and Coughlan 2018; Morgan and Dowling 2019). This is particularly true in areas with very high camera coverage, such as public transport networks. A recent study in Sydney, Australia, found that police requested camera footage from the operators of cameras monitoring the metropolitan rail network an average of 17 times per day. There is also growing evidence that access to footage helps police to solve crime. Ashby (2017) analyzed more than 250,000 crimes recorded on the British railway network over a 5-year period. He found that CCTV was available to investigators in almost half of all cases and was useful in two thirds of cases for which it was available. Moreover, when the CCTV was useful, the likelihood that law enforcement was able to solve these cases improved. Most recently, Morgan and Dowling (2019) showed that police access to CCTV footage, when investigating crimes on the rail network, improved the chances that an offender would be arrested, especially for property crime and late-night assaults. In a related study, footage was highly valued by investigators as it typically aided in their ability to identify or confirm the identity of a suspect (Dowling et al. 2019). Footage was most likely to be sought when other forms of evidence – specifically, witness statements – were not available (Morgan and Coughlan 2018).

Results tend not to be as positive in other locations, such as city centers, where the level of coverage is not as great. Kindgren and Marklund (2014) found that police sought access to CCTV footage for one in eight incidents that occurred in a two nighttime entertainment districts in Sweden, providing information relevant to the investigation in one in four cases. Likewise, King et al. (2008) examined the use of public space CCTV footage by detectives in San Francisco, finding that police only charged an offender in six of the 120 cases where footage was requested over a 3-year period.

In terms of the impact of video surveillance on physical security – whether in reducing crime, improving perceptions of safety, or helping police – results are mixed. But the research does show several factors influence whether CCTV is effective. Specifically, the type of crime being targeted, the level of coverage in public areas, the ability of cameras to capture entire incidents, the resolution and quality of images captured by CCTV, the amount and type of monitoring in place, the relationships between police and camera operators, and the presence of other security measures are improved through use of CCTV (Ashby 2017; La Vigne et al. 2011; Levesley and Martin 2005; Piza et al. 2019). Moreover, this information can be used to shape the ways in which video surveillance networks are designed, used, and managed.

Determining the Appropriateness of Video Surveillance

First and foremost, the evidence presented in this entry highlights the importance of careful

planning, starting with the decision as to whether video surveillance is the correct choice. Whether the goal is to prevent crime or to assist police investigate crime, CCTV should be installed in locations where there is a high concentration of criminal incidents. Additional consideration needs to be given to the types of offenses that occur in that location. The preventative benefits of CCTV appear limited mostly to property offending and possibly drug dealing and do not extend to preventing violent crime (Piza et al. 2019); however, police are more likely to seek access to CCTV footage for serious violent crime, while both property and violent crime investigations benefit from the availability of CCTV footage, albeit in different ways (Ashby 2017; Dowling et al. 2019; Morgan and Dowling 2019). Hence, CCTV is probably not the answer when the aim is to reduce (rather than investigate) a violent crime and disorder problem in city centers; but it may be the appropriate choice when the problem is crime in suburban areas or car parks. In any case, CCTV is most effective when used in combination with other intervention measures, including signage, lighting, security guards, and access control (Piza et al. 2019), which means it should be considered as part of a wider strategy to reduce crime.

Design Features of Video Surveillance Systems

Once it has been established that installing a video surveillance is an appropriate response, then the next step is to establish the requirements of the system, including technical specifications. This process includes details, such as the placement and positioning of CCTV cameras and the type of cameras that are used. Decisions will be influenced by the reasons for installing the system (and intended outcomes), as well as the specific characteristics of the location in which CCTV is to be installed.

A site audit will assist with respect to the layout of cameras to ensure adequate coverage. Camera coverage has been shown to have direct implications for the effectiveness of video surveillance both in preventing crime (Piza et al. 2019) and in enhancing criminal investigations (Ashby 2017; Morgan and Dowling 2019). However, the benefits appear limited to areas where it is possible for cameras to cover a large proportion of public space in a given area, whether that is a small location, like a car park, or bigger, but well-defined area, like an entire public transport network. Related to this issue is the placement of cameras – immovable obstructions to the line of sight of cameras not only impede the use of footage for investigations (Dowling et al. 2019), they are also associated with reduced prevention effects (Piza et al. 2014a). The presence of other forms of passive surveillance is also an important consideration because this will influence the availability of other evidence (i.e., witness statements; Morgan and Dowling 2019).

Image quality is obviously important, particularly with the use of video surveillance footage as evidence in criminal investigations. Studies have shown that when the quality of footage falls below a certain threshold, there can be a significant negative effect on the ability of operators to identify individuals captured on CCTV accurately. Keval and Sasse (2008) concluded that the optimal frame rate for detecting events and the analysis of events using video surveillance footage was eight frames per second, significantly lower than the industry standard for modern cameras. In selecting the appropriate equipment, it is useful to consider the range of requirements in terms of image quality, ranging from the need for sufficient resolution for crowd control through the ability to identify faces at a distance. The decision will be based on four factors: object to be observed, the level of detail, distance between object and camera, and lighting conditions. Compromises are, of course, necessary. Image quality is constrained by the quality of cameras and camera lenses (and equipment generally), the choice of which often depends on budget. But it can also be influenced by the level of video compression required to store images and the amount of storage available, which is, in turn, influenced by the length of time needed to store images (before they are recorded over). It is essential to ensure that decisions to maximize storage, for example, do not

come at the expense of image quality in such a way as to render the footage useless to investigators.

There is good evidence regarding the importance of ensuring that video surveillance systems are integrated with law enforcement responses (Alexandrie 2017; La Vigne et al. 2011; Piza et al. 2014a). Proactive enforcement of crimes detected on camera is a key factor in whether CCTV actually prevents crime, with the presence of active monitoring shown to increase the efficacy of video surveillance as a crime prevention measure based on dozens of studies (Piza et al. 2019). While the mere presence of CCTV may be sufficient to deter opportunistic offenders, the increased threat of arrest that comes from proactive enforcement may enhance this deterrent effect (Piza et al. 2014a). Footage must also be shared in a timely fashion post-incident; research suggests that the vast majority of footage requests are likely to be made within the first week following an incident (Morgan and Dowling 2019). Footage needs also be provided in a viewable format, since the inability to view images because of compatibility issues can hinder investigations (Dowling et al. 2019).

Of course, this result is conditional on an effective relationship between camera operators and law enforcement, but also may be attributed to the system design. In their large-scale observational study of control rooms, Gill et al. (2005) concluded that the design of control rooms had a significant bearing on how well they operated. Of particular note was the importance of camera-to-operator and camera-to-monitor ratios – the probability of detecting incidents declined substantially when the ratio of cameras to an operator exceeded 100. Likewise, a major contributor to the effectiveness of the surveillance network used on the train network in Sydney, Australia, was the ICT system that enabled rapid information sharing and communication between the security personnel working in the control room and the dedicated law enforcement officers and security staff able to respond to incidents (Morgan and Coughlan 2018). Integrated networks, such as where a video surveillance system is connected with the police radio network, allow for effective communication between camera operators and frontline responders (Gill et al. 2005).

However, effective implementation of video surveillance does not end at the design stage. Individuals and organizations that are responsible for procuring CCTV systems, distributers and installers, and camera operators each play an absolutely critical role in ensuring video surveillance is used effectively. The human element of video surveillance is an essential and sometimes overlooked consideration (Ratcliffe 2011). Research has tended to focus on the role of camera operators since actively monitored systems appear to be the most effective at preventing crime (Alexandrie 2017) and in extracting evidence for investigations.

There are different models in terms of who monitors CCTV footage, including police (which is rare, at least in some countries like Australia), security personnel, local government staff, and volunteers (Wilson 2005). Each model has advantages and disadvantages. In many jurisdictions, including in the United Kingdom and Australia, CCTV camera operators responsible for public space CCTV must possess a relevant security license, which mandates participation in accredited training for security personnel. The same is also true for installers of video surveillance systems. In the United Kingdom, operators must also obtain a frontline Public Space Surveillance license, which requires the completion of Security Industry Authority-accredited training. Training standards and packages specific to video surveillance exist in most countries, delivered by accredited training providers, but there are barriers to access, such as cost and awareness of availability (see ▶ "Physical Security: Methods and Practices" and ▶ "Security Guards: Academic and Training Programs" in this encyclopedia). Research has shown that operators often do not receive the training they require, and that factor negatively impacts the performance of video surveillance systems (Gill and Spriggs 2005).

Whether as part of mandatory licensing requirements or not, best practice dictates that camera operators should be provided with training in a range of areas, including training that

can enhance their performance as operators and technology or product-specific training (see ▶ "Physical Security: Best Practices" in this encyclopedia). Key areas for training, besides the obvious practical training on how to operate the system and camera equipment (and knowledge of CCTV generally), include effective monitoring practices, such as how to identify suspicious behavior, people, or objects, legislative and privacy obligations (which includes data storage and handling), effective communication, and the processes for storing and retrieving footage for investigative purposes. The importance of handling video footage appropriately so that it remains admissible in court as evidence cannot be overstated.

Managers are also vital, particularly in larger control rooms with multiple operators. Managers with technical expertise are able to liaise effectively with security contractors and operators and to share knowledge on system operation (Gill et al. 2005). Training for end users of footage may also prove beneficial. La Vigne et al. (2011) found support for training for prosecutors and defense attorneys in the use of video surveillance systems, system capabilities (and limitations), and presentation of footage when used in the courtroom.

Beyond training, it is also important that there be well-designed operational procedures for the effective monitoring of video surveillance, storage of camera footage, and sharing of footage for the purposes of criminal investigations. These protocols must align with relevant jurisdictional policies and legislation. They also make clear the responsibilities of camera operators and end users with respect to matters such as who is allowed to access to real-time and recorded footage, and in what circumstances, when this footage may be shared with third parties, and how to handle the disclosure of privacy breaches and processes for the effective management of video evidence. Certain procedures, such as those relating to video evidence, should be developed in close consultation with local law enforcement. Operational procedures should extend to protocols regarding the continuous length of time that operators spend monitoring footage, given the impact of mental fatigue on task performance (Faber et al. 2012), as well as the support provided to operators who witness traumatic or distressing footage to mitigate its harmful effects (Smith 2016).

A final important consideration with any video surveillance system is balancing the need for and potential benefits of surveillance with the need to respect the privacy of individuals. Privacy advocates and academics have long raised concerns about the impact of mass surveillance, particularly in circumstances in which video surveillance systems are connected with other technology, such as facial recognition systems.

While these issues are important, there are ways to protect the personal information collected via video surveillance systems. First and foremost, video surveillance systems must adhere to relevant planning and legislative guidelines. Each country has its own legislation, governing principles, or code of conduct for the use of CCTV, particularly as it relates to privacy. For example, the UK Government has released a Surveillance Camera Code of Practice (Home Office 2013), while in Australia the legislation varies between the states and territories and for different industries. Beyond these, there are general principles that help guide the ethical use of video surveillance for physical security. The European Forum for Urban Security (2010) has published a set of principles for video surveillance systems, designed to help ensure that the rights of citizens are appropriately protected. This includes ensuring that the use of video surveillance can be justified empirically, that the equipment is proportional to the problem it seeks to address, that the purpose and process for installing CCTV are transparent, that there is a process of accountability to the public, and that there is some degree of independent oversight. These provide useful guidance to those organizations planning on installing CCTV systems.

Conclusion

Video surveillance remains a popular physical security measure to serve the goal of preventing

crime or assisting police in response and investigation. Although there remains mixed evidence as to its crime prevention effects, there are clear benefits to law enforcement and security providers. When deployed strategically there is also good evidence that it can be effective in improving public safety and security. It is important, however, that video surveillance systems adhere to best practices with respect to their design, management, and operation.

Police: Public Versus Private Policing

Policing · Public versus private · Security · Investigations

Definition

Public and private initiatives to respond to disorder and crime.

Introduction

Policing is a very wide, and expanding, concept. While it naturally has a strong connection with "the police" as the entity for the execution of the monopoly over legitimate use of force by the state, policing as a concept goes much further than just the actions of the public police. For example,

policing may involve regulatory agencies (see, e.g., Mascini and Van Erp 2014), civilians (see, e.g., Van Steden 2009), and private security firms (see, e.g., South 1988). In this contribution, the concept of policing will be unpacked. In current society, "policing" can no longer be seen as the sole responsibility of any state actor, and so, both the public and the private side of policing are discussed.

High Versus Low Policing

Policing as a concept can be considered contested. First of all, there is a difference between high and low policing that is often not made in our day-to-day use of the concept. The origins of modern police are often placed with the efforts of Sir Robert Peel in the United Kingdom in the early nineteenth century. This type of policing is the "low policing," which we associate with the police organization. It consists, according to Brodeur (1983: 512), of "the forceful reaction to *conspicuous* signs of disorder" (emphasis in original). Low policing consists of the first line of defense against crime and disorder, by providing emergency assistance, reacting to signals from the public, controlling traffic, nightlife, and events, and by providing crowd control. "High policing," on the other hand, concerns itself with *political* policing. In the words of Brodeur (1983: 513), "it reaches out for potential threats in a systematic attempt to preserve the distribution of power in a given society." High policing is about gathering intelligence to ensure the stability and security of the state, rather than about security and safety of (parts of) the population (for a discussion of the difference between safety and security, see ► "Security: Concepts and Definitions"). This type of policing is usually not associated with the police but rather with national intelligence services.

Public Versus Private Policing

Going back in time, we can see that policing has a long history. Only in recent times have "policing" and "security provision" come to be seen as an exclusive task of the state (Garland 2001). Before the development of a modern, state-led police force, the provision of security was something that was a shared task of public and private entities. In most nation-states, an official police force has only been around for about 200 years (ibid.). With the professionalization of state policing, private forms of policing were increasingly diminished. However, even in these times, social control has never been merely state business. "Social control" may be defined as "the capacity of a society to regulate itself according to desired principles and values" (Sampson 1986: 277). This contains both formal (organized by the state) and informal (executed by private individuals and entities) forms of social control. While most of the *formal* policing might have been monopolized by the state in the last couple of centuries, *informal* policing (within families, companies, schools, etc.) remained present throughout history.

In more recent years, the involvement of private parties in policing has grown immensely (Button and Stiernstedt 2017). While the involvement of private parties in policing is by no means new, the development of a professional, commercial security market is (Shearing and Stenning 1983). Different perspectives are taken by different scholars as to the question of what caused such a development; however, most fall under one of two categories. On the one hand, there are those who focus on a "failure of the state argument" (also known as "fiscal constraint theories"). Because of restrictions in funding, state police organizations are unable to cope with the demand for security, arising from society (Jones and Newburn 1993). As a response, the state privatizes some of its functions to private parties, so as to release some of the pressure. Another strategy to solve the policing deficit is to "responsibilize" others to participate in policing. In this way, the state is able to avoid ceding its position to the private sector: while responsibility is shared, this is done under the banner (and on terms) of state policy.

In addition to these fiscal constraint theories, focusing on a receding state, there are those who see the growth of mass private property as the major force behind the expansion of private

policing (Shearing and Stenning 1981). In our current society, the line between public, private, and semipublic space gets blurred. Many daily activities now occur on (mass) private property, such as amusement parks and shopping malls. Both public and private policing occurs in these (semi)public and private spaces, and so power and responsibilities get fragmented and divided among public and private actors. Complex networks of policing combine to provide security within a society.

The difference between these perspectives is mainly the origin of the growth. Fiscal constraint perspectives lay emphasis on a gap that is created by a receding state and filled by private policing. Mass private property perspectives, on the other hand, state that there is a growing demand for security in (semi)private spaces, which logically leads to a growth in forms of private policing (Button 2004).

Another development that is important here is that of the shift toward "community policing." Although community policing as such is not new, it became very popular at the end of the twentieth century (Emsley 2007). Its popularity can be attributed to the existence of problematic police/community relations in many countries. Community policing is a very broad scope concept that can be used for many initiatives. It is often seen as more of a philosophy than a concrete program, which tries to focus on problem-solving within communities, with the use of partnerships (Cordner 2014). These public/private partnerships consist of police and other state actors and communities (e.g., neighborhoods) but also of different forms of private (commercial) policing.

Public and Private Policing Functions

While state-led policing can be divided into high and low policing, additional categories can also be identified. Within the policing task, there is, for example, a division between preventative (before the fact) and repressive tasks (after the fact). This distinction may also be made within private forms of policing. Before the fact private policing focuses on various aspects of security and safety, such as physical security (cash-in-transit, guarding of personnel or guarding of specific places such as an embassy, event, airport, the railway, maritime security, or a mall by security guards) or technical security services (such as alarm systems and camera surveillance and cyber security). After the fact private policing consists of private providers of corporate and investigative services, responding, for example, to instances of fraud or employee theft (for more on this, see ▶ "Investigations: Employee Theft of Employer Property").

The broad concept of "policing," being executed within both the public and the private sphere, often evokes heated debates on the question who should be responsible for policing. In criminology (and indeed, in Western society more generally), a tendency exists to place the emphasis on state efforts. As discussed above, many private forms of policing exist, and to expect the state to be the sole provider of security and policing services is not very realistic. Few scholars call for a situation in which policing is the sole responsibility of the state. However, the question does remain whether the state needs to be the primary actor in this or just one of the many policing localities (see ▶ "Security: Concepts and Definitions" for a brief discussion of this).

A point of principle in this debate is the argument that policing for profit by private security providers does not align with the common good focus of public police agencies (Loader 2000). Interestingly, recent research points in a direction that the division between public and private, in the sense that "the public police is working for the common good" and "private security is promoting private interests," paints a too black-and-white picture. In their 2018 article, Loader and White claim that security cannot be said to be a strictly "discrete commodity": private security guards are regularly confronted with situations in which private interest and public interest collide. One example of such a situstaion is one in which a security guard prevents a suicide attempt of someone while he is not hired to do so. Private interests and moral obligations are often weighed against each other, even within the commercial context of private policing. Meerts (2018) reports similar results when it comes to corporate investigators.

In the plural landscape of policing, drawing very clear distinctions is a complex endeavor.

Conclusion

The answer to the question of what "policing" actually is, is ever-changing. Policing can be seen with a narrow lens, merely consisting of the actions of the public police organization. This focus would then be on low policing by the state. However, over the past decades, the concept has been broadened to also include many activities by intelligence agencies (high policing efforts), regulatory agencies, and others. But not only is the concept of *what policing is* liable to change, so is the answer to the question *who executes* the policing activities. We now have a pluralized policing landscape, in which both public and private forms of policing are omnipresent. It remains a question for the future which direction policing is going to take – however it seems a safe bet that the concept will remain liable to change.

Definition

A private detective also termed "private investigator" (PI) is a person who is a fact finder or evidence gatherer and is hired directly by businesses (e.g., law firms, corporations, insurance companies) or individuals to gather intelligence and confirm or disprove information.

Introduction

PIs are, at the most basic level, information-gatherers. Their job is to find information about persons, places, and things on behalf of clients. Finding the information can involve a wide range of activities, from interviewing people in broad daylight, to conducting undercover surveillance late at night. Most of the time, however, the primary business of a PI involves knowing where to look or whom to contact for information. And while today, quite a lot can be found online, the stock and trade of a private investigator is the ability to reach out – personally – to someone who will have the information they need.

Because the job of a PI so often involves obtaining information from others, the essential quality of a successful PI is the ability to relate to other people. They also should possess a broad knowledge of human behavior and have an inquisitive mind. Given that these traits can be picked up in a variety of settings, private investigators come from all walks of life.

At one time, it was uncommon for anyone but a former police officer to be a private investigator. Now, however, attorneys will sometimes move into investigative work, or a PI may come from an entirely different field such as psychology. In fact, private investigators can have almost any sort of educational background, with the most common degrees being in security management, criminal justice, psychology, or even history. Nevertheless, the best investigators have some education specifically in investigations. Some colleges offer credit courses and training in criminal and private investigations, and it is best for a PI to have exposure to both. However, a lack of formal training can be supplemented with – and enhanced by – field experience working with a detective agency or law enforcement or as a paralegal or news reporter.

In most states, to solicit business and practice, a private investigator/detective must have a state license. The most current state requirements can be accessed through the website of IASIR (The International Association of Security and Investigative Regulators) www.iasir.org. Because licensing is conducted on a state-by-state basis, licensing requirements vary. However, most states require PIs to be at least 25 years old, have a high school diploma (or the equivalent), have US citizenship or residency, and pass a test. States might also mandate up to 3 years' experience working in law enforcement, investigations, or another full-time job. Most states also require a private investigator to get a bond, which protects the state from being liable for improperly issuing a license.

Finally, it is essential for a PI to have a clean record. Some states will refuse to issue a PI license to candidates who have a felony or misdemeanor conviction. Clients will also often look for other indicators of responsibility and reliability. A potential client conduct a Google Search, but they may also wish to verify that the investigator does indeed

possess a PI license, to see evidence of any professional memberships. Work history also points to whether the PI is responsible and reliable. Many of the best PIs do not advertise at all.

Clientele and Ethics

Private investigators work for attorneys, corporations, courts, and individuals. They are hired by companies to research personnel, such as pre-employment investigations; they may also be asked to help conduct due diligence for business acquisitions or mergers. However, PIs are most often hired by attorneys because they possess complementary expertise that the attorney needs to bring a successful conclusion to a case. Attorneys often need information to determine whether an accused person has a reliable alibi, finding a witness or they need hard-to-obtain details to reconstruct an accident. The PI is then hired to obtain this information.

Private investigators accept cases based on a variety of factors. The most well-regarded PIs turn down more cases than they take, sometimes because the scope of the work is not within their expertise, but more often because prospective clients are not willing to pay what the PI deems their time and services are worth. Personal values and legal ethics also influence what work a PI is willing to take. Some individuals may approach a PI to help them break the law – to conduct inappropriate surveillance in order to circumvent a restraining order, for example. Even attorneys are not always ethical; for instance, an attorney might ask a PI to pose as a law enforcement officer to obtain information or to sign an affidavit that the attorney, not the PI, has prepared. In effect, investigators should be as discerning as their clients when choosing who to work for, and just because they can find information does not necessarily mean that they should.

Cooperation with Law Enforcement

Private detectives can cooperate with law enforcement officials. In some instances, these partnerships are official and long-lasting. The PI will initially investigate a case and then turn it over to law enforcement. In one example of such a situation involving trust funds, one trustee claimed to have lost some money in a bad business deal, but other stakeholders suspected that the money had been stolen. These stakeholders approached a law firm, who then hired a PI (who specialized in fraud) to work through stories of how the business deal went bad. Ultimately, the PI uncovered multiple phony corporations and determined that the trustee had lied and had stolen the money. The attorneys then took the case to law enforcement.

Specializing

Becoming a truly top-notch detective – and in turn being able to command the highest hourly rate – requires expertise, or specializing, in a particular area. According to a survey by PInow.com, some of the most common specialties are background checks, civil investigations (gathering evidence for a civil trial), surveillance, and fraud (Faber 2013). By specializing, a PI can solicit a specific type of client, or they can transition into related fields (e.g., polygraph examiners or cybercrime investigators).

Training to become an expert can be done in a variety of ways. For instance, before striking out on their own, a PI may take training courses while working in law enforcement, serving in the military or working for a private investigations firm with a particular specialty. Organizations (e.g., American Society for Industrial Security [ASIS], Association of Certified Fraud Examiners [ACFE]) offer certifications in investigations and fraud examination. Other organizations offer qualifications in arson investigations and accident reconstruction. These associations train individuals in a given specialty and then typically require testing, years of field experience, and at least a bachelor's degree to become certified.

Expert Witness

To become known as an "expert" in a given area, a PI needs extensive experience, a reputation as a

knowledgeable specialist, training, and credibility earned through the accolades of other professionals working in that area. To be deemed an "expert," a judge accepts the PIs' credentials and allows the PIs' testimony in a trial. When this happens, it means that the court has considered the PI to have the knowledge and expertise necessary to satisfy a judge in a particular case. Sometimes, the judge requires an investigation to be done to determine if a theft has occurred and if so, who is responsible. For example, a guardianship case might require an investigation to determine if a guardian is stealing from an elderly client. The court "hires" the investigator and pays them for their services. An expert PI may also work directly for an attorney, either prosecution or defense, as a "testifying expert." In this case, the PI is paid to take the stand in court and answer very pointed questions – some of which may attack the investigator's credibility. Not every PI finds this type of work desirable, but it is one way to charge a higher rate for having acquired a certain level of expertise.

PIs can take on the role of a consultant, charging an hourly rate to read over all of the documents in a case. If they disagree with the basic premise of the argument, they will be paid for identifying holes in the case by an agreement, but they need not continue to testify for that attorney and their client. This might happen where an individual has been accused of committing a crime. As an expert witness, the PI may be called upon by the attorney to say that the evidence indicated that the defendant is not guilty. However, after reading all of the materials, the PI believes that the individual is guilty, in which case it would not be appropriate for the expert to testify for the defense.

Why Hire a Private Detective?

The role of the private detective has become more complicated in the last two decades. The legal needs of private citizens and the corporate world have expanded, public law enforcement's numbers have not kept up, and as a result, the responsibilities of each civil servant working within the police force have broadened. Law enforcement has increasingly turned its attention – and has allocated its resources – to violent crime and counterterrorism (The Department of Justice, Office of Public Affairs 2011). This shift in attention has left lesser criminal, civil, and administrative investigatory responsibilities neglected, and as such, private citizens and corporations who are unwilling to wait for law enforcement to "get around" to investigating their issue have turned to private detectives.

Besides impatience with public law enforcement, another reason private citizens may be inclined to hire a private detective is that of his or her ability to handle the overlap in "type" of an investigation. For instance, a PI could be working on a case of corporate insurance fraud and discover that there is a criminal conspiracy that goes well beyond the insurance claim that the company initially hired the detective to investigate. Similarly, a missing person's case might turn into something very different if the private investigator discovers that the individual has been murdered.

Missing person's cases are the perfect example of work that is ideal for a PI rather than a civil servant detective. Law enforcement will not look for a missing adult unless there is some evidence of foul play or diminished capacity; however, PIs – if they accept the case – will look for a missing person under virtually any circumstances. Therefore, a family or attorney might hire a private investigator to locate a person because they wish to settle an estate, or an adopted child (now an adult) may want to find their biological parents – cases that a detective working for law enforcement would never take.

Casework Examples

Many private investigators say that their reason for being in the business is the unexpected nature of the casework they get to pursue. Their work is limited only by the legality of what the client wishes to pursue, the client's budget, and the skills and experience of the investigator.

The following real-life cases illustrate the depth and breadth of work an investigator may undertake. All of these cases have been made

public through court documents; in no instance did a private investigator violate his or her oath of confidentiality by sharing details of the case. However, some names have been changed to maintain privacy.

Case 1: Mary James, Sole Residence
Susan Pickman, NYS Licensed Private Investigator, and Certified Fraud Examiner

In most investigative cases, the key is to know which research tools to use and to persist in using them until some lead takes the investigator to the data required. This is how Susan Pickman, a New York State licensed private investigator and former police officer, pursued and solved the primary residence case of Mrs. Mary James.

Mrs. James was a senior woman who received subsidized housing in Europe. The landlord, John Jones, claimed that she was living elsewhere, which violated her legal requirement to live in the apartment as her sole residence. Mr. Jones wanted to revoke Mrs. James right to the property, but first, he needed to prove that Mrs. James was living in another country. He required an NYS licensed private investigator, which is how he hired Susan Pickman.

Pickman began her search for evidence of Mrs. James' residence elsewhere by looking through a number of public and proprietary databases. She found no trace of the woman, but she did discover an address for her son. By visiting this residence, Pickman found Mrs. James living there, and her affidavit was enough to allow European courts to issue a finding in favor of Mr. Jones.

Private investigators must often look tenaciously and use inconvenient or unconventional means to find the answers they seek. Thus, a great PI must have a voracious appetite for research and a keen ability to make links between seemingly unrelated information.

Case 2: Jack Patch, Missing Person
Charles-Eric Gordon, Esq., Investigative Counsel

While private investigators tend to specialize, most take at least one missing person's case. Such is the case of Jack Patch. This case was pursued by Charles-Eric Gordon, a New York State licensed attorney who conducted investigations into matters with a legal connection. (Due to being a licensed attorney, he was exempt from needing a private investigator license [Application of Article, NY GBS § 83].)

In 1988, Gordon was hired to investigate the disappearance of Jack Patch, the husband of Sarah Patch, who had recently died. Sarah and Jack had separated before Sarah's death, but Sarah set up a testamentary trust that would pay a generous amount of money each year to Jack, as long as he never divorced her and never married anyone else.

Checks from the trust had been delivered to a PO box in Manhattan – and cashed – for years until, in 1986, the PO box was suddenly closed with no forwarding address. The estate manager needed to either find Jack or confirm his death and locate next of kin, and so he hired Gordon.

Gordon began his investigation by consulting the white page directories and calling every listing with the name Patch. Eventually, he connected with Jack's brother Joseph, who shared that Jack had been born in 1898 and was buried somewhere on Staten Island. Because Gordon knew that Sarah, Jack, and their families were Jewish, he called Jewish cemeteries until he located Jack's grave.

As he awaited Jack's death certificate, Gordon continued to seek out Jack's next of kin. The cemetery records had listed a second wife, Ida, but when Gordon tried to locate her, he was unsuccessful. Instead, he found and spoke with Jack's nephew David, who implied that Jack and Ida had been married before Sarah died. To confirm this, Gordon once again used telephone directories to hunt down Jack's daughter Randy. Randy ultimately confirmed that her mother (Ida) and father (Jack) had had a bigamous relationship, which defrauded the trust since bigamy was and still is a felony in New York.

What makes Gordon's investigation particularly interesting is that it occurred in 1988 and 1989, before the Internet and online proprietary databases. Consequently, it involved a lot of telephone work and writing away for public records. This legwork is important to note, because while a lot of data is accessible by computer today, it would be misleading to assume that this cuts down on the amount of research involved in a PI's job. In fact, a lot of online data is wrong and must, therefore, be carefully double-checked for accuracy and to ensure that no "red herrings" lead the investigator astray.

Case 3: Bob's Carpets, Arson
Bruce H. Hulme, Certified Fraud Examiner and Board Accredited Investigator

This case was about whether the owner of Bob's Carpets, a carpet factory in Dalton, GA, had hired an arsonist to burn it down so that the owner could collect from the insurance company. The insurance company had determined that the fire had been set intentionally, but the owner's alibi was airtight, so the insurance company hired Bruce H. Hulme, a certified fraud examiner and board accredited investigator, to identify the arsonist and ascertain if the owner had hired him or her.

When Hulme eventually located the professional arsonist in New Jersey, arrangements were made for his arrest by the Georgia Bureau of Investigation, and he was given immunity to testify against Bob, who he stated had hired him. However, the trial was to take place in the US district court for the Northern District of Georgia in Rome, and the law firm representing Bob was a "The Northern Georgia law firm representing Bob (a "Good Ole Boy")," whereas the insurance company, based in New York, had hired a "Yankee" firm. Consequently, the insurance firm lost the case, in spite of Hulme's having identified the arsonist and acquired his confession.

The lesson from this case is that investigative work – even successful investigative work that uncovers the evidence a plaintiff or defendant needed – does not always result in the legal case being won. Hulme was hired to investigate an arson case, and while he successfully verified that arson had, in fact, been committed and identified the perpetrator, his side still did not win the court case.

Conclusion

Private detectives are needed now more than ever before. Whether they work with law enforcement, legal counsel, corporations, or private individuals, the job of a PI is to persevere in finding information that others do not have the means, skills, or time to unearth. The work can be both tedious and challenging and requires both a voracious appetite for detail and the ability to engage and observe others. While PIs can come from a variety of professional and educational backgrounds, almost all will need field experience and a state license to work as a professional private detective. Once they obtain a license, PIs can continue with formal training and solicit particular work to specialize in an area like fraud, arson, or civil investigations. Specializing can then lead to cooperation with certain types of law enforcement or attorneys and can also result in being called as an expert witness in civil and criminal trials. Finally, no matter the client, a PI should always exercise discretion in deciding whether or not to take a case; just because they can find something or someone does not always mean that they should.

Protection and Security in Public Spaces

Spyridon Triantafyllou
John Jay College of Criminal Justice, New York, NY, USA

Protection · Public spaces · Security · Safety · Openness

Definition

Measures to suggest, establish, and implement for public safety in non-private locations.

Introduction

Public safety is highly prioritized in political agendas because the sentiment of security affects public opinion. Especially after the 9/11 terrorist attack, much emphasis has been placed by public authorities on recommending, planning, and implementing security and safety countermeasures in order to protect the public.

Research has shown that, over the last two decades, private interests and security in public spaces have changed public spaces to regulated places of consumption (Low and Smith 2006). Public social life increasingly falls within privately controlled spaces policed by security officers operating not in the public interest, but in the interests of their employers or corporate clients. Security in public spaces is thus connected with formal social control, projected mainly by manned security, such as security guards and other personnel and security devices, such as CCTV (Iveson 2007).

Defining Public Spaces

In order to define the term "public," the traditional dichotomy cleavage "public – private" is useful in the context of this analysis. *Public spaces* are places where individuals can claim full rights of access, use, action, and appropriation (De Backer et al. 2016). However, public spaces (e.g., shopping malls, park benches, and public streets) can be fully or partially controlled by limiting the extent of the openness of these spaces (i.e., *quasi-public spaces*, such as malls or other downtown areas) (Altman and Zube 1989; Jackson and Valentine 2016).

The origin and role of control is also connected with the notions of ownership and openness in relation to the "public–private" dichotomy. According to Wakefield (2003), there are four types of spaces based on this dichotomy: open public spaces; restricted public spaces; open private spaces; and restricted private spaces.

Open public spaces are spaces that are publicly owned and freely accessible. However, whether a member of the public may claim a legal right to enter such spaces depends on the type of space. Such a right exists in relation to access to public highways, and to open spaces, such as parks and recreation grounds, when public rights of way are set out in the statutory provision for those spaces (Wakefield 2003).

Restricted public spaces are publicly owned and access is only offered to those who fulfill certain admission criteria. These places may include publicly owned facilities at which an entry fee is charged, such as a leisure center owned by a local authority. Since a fee is required to restrict access, those who pay the fees can

access the space. Moreover, the restrictiveness of access depends on the space. For example, hospitals and military establishments have restrictive criteria for access (Wakefield 2003).

Open private spaces are privately owned territories, where free access by any visitor may be seen as implicit since visitor may claim no legal right of access to the premises unless it contains restriction of way. It is common to differentiate *public spaces* in general from *open private spaces* that are used for commercial purposes (i.e., shopping centers, leisure parks, passenger airports owned by private companies, and some business parks) (Wakefield 2003).

Restricted private spaces include private residencies or dwellings and privately controlled recreational areas where entry fees are charged (i.e., cinemas or football clubs) and/or membership is required (i.e., health or social clubs) (Wakefield 2003).

Analyzing Security as Element of Protection

For purposes of analysis and discussion, the concepts of "security" and "(life) safety" are to be taken into consideration. Although these terms are distinctly approached, they are closely interwoven and interdependent, and oftentimes they appear to be the same thing. In doing so, the notions of "security" and "safety" might provide useful insights about the concept of "protection" as a whole in public domain. Security is mostly related with crimes, while safety is mostly related with fires and accidents.

> [S]ecurity (derived from the Latin word *securus*) means "the state of being secure; freedom from danger or loss" (McCrie 2007) and has numerous definitions implying a stable, relatively predictable environment in which an individual or group may pursue its ends without disruption or harm and without fear of such disturbance or injury. Safety, or life safety, or fire life safety, (derived from the Latin word *salvus*) means "the state of being secure; freedom from danger" (McCrie 2007) and has similarly numerous definitions which involve minimizing the possible danger to life and property from various threats. (Craighead 2009)

Security refers to protection and involves enforcement and suppression, while *life safety* refers to care and involves medical care and emergency response. But, in general, despite that these concepts are not well conceived in colloquialism, people usually are able to connote security with law enforcement agencies (i.e., police departments), safety with emergency services (i.e., fire departments), and, therefore, they are able to assume protection in total which includes both security and life safety.

Focusing on public spaces, the distinction between "security" and "safety" is of paramount importance. It is critical because not only does it enable us to know if an emergency arises, which is its nature and who is responsible for that (i.e., a police department or a fire department), but it also helps us to mitigate risks deriving from several situations by assessing the relevant threats.

From a security perspective, there may be threats such as crimes, active-shooting situations, suicide-bombings, cyberterrorism, or CBRN attacks, while from a safety perspective, there may be threats such as fires, natural disasters, traffic accidents, or communicable diseases. A threat is any indication, circumstance, or event with the potential to cause loss of or damage to an asset (FEMA 2005). Threats may be intentional, accidental, or natural disasters, while some of these threats may be considered asymmetric in nature.

The boundaries that characterize the private and public spheres are blurred in a risk society because of directives from institutional and state levels that often emphasize personal responsibility. However, public spaces become an even greater source of insecurity in a risk society (Van Brunschot and Kennedy 2008). An important tool for determining the "security" and "life safety" needs of an asset is risk management. Therefore, the distinction of security and safety is valuable for methodological purposes in terms of identifying vulnerabilities of assets, especially if these

assets are publicly accessible or located in a public space.

According to the law and standards in place, it should be obvious who is the authority having jurisdiction when a security or a safety issue occurs. Also, it should be clear who are the competent police or fire departments to operate in a public space which allows the agencies to perform in a superior manner, both in operational and strategic level.

Methods for the Protection of Public Spaces

This section aims to provide a generic methodology including all four spaces as mentioned above, rather than focusing on one specific type of public space. The methods suggested are supposed to be practical and help readers understand how public spaces are protected and secured.

According to Garcia (2006), when designing (or changing or updating) the physical protection system of a public space, the information gathered by a security management expert should include: the (a) physical conditions; (b) facility operations; (c) facility policies and procedures; (d) regulatory requirements; (e) legal issues; (f) safety considerations; and (g) the goals and objectives of each organization tasked with the protection of the public space.

First of all, it is imperative to request information about the physical conditions and physical infrastructure of facilities. The information provided to the security expert or other person or agency responsible for protection of public spaces should include: the site boundaries; the complexity of facility, areas, and other sub-areas; room locations within the facility; access points; existing physical protection features (if any); and all infrastructure details, such as heating, ventilation, and air conditioning system (HVAC) system, communication paths, construction materials of walls and ceilings, locations of any hazardous materials, and exterior areas. Information about the existing physical protection system, including (but not limited to) fences, sensors, cameras (CCTV), entry control systems, barriers, response force availability, should also be provided (Garcia 2006). Finally, it is crucial for security professionals to be apprised of whether the facility utilizes a contract or proprietary security force (if any) and its capabilities (Garcia 2006).

Second, the security expert should be aware of facility operations, including daily operations, employees, units, and divisions without the organization and operating conditions (working hours, off-hours, emergency operations), as well as the types and numbers of employees involved or affected by security operations. The existence or implementation of a security system may affect or restrict the work of the facility. Moreover, the supporting functions are to be evaluated, including procurement procedures, computing resources and distribution, maintenance activities, asset tracking, operational involvement and location of senior executives, workflow, shift changes, employee benefits, shipping and receiving, accounting functions, and any other supporting functions. Finally, information regarding the transition periods at the facility, especially during the shift change, if applicable, and the vehicle activity into and out of the facility, should be obtained (Garcia 2006).

Third, the security expert must know and understand all written and unwritten policies and procedures throughout the facility. In doing so, the expert can identify whether the occupants follow such policies revealing any lapses in order to update or modify these policies to mitigate risks and reduce liability. In any case, security managers must agree not to divulge any information, classified or not, related to the facility. In addition, corporate policies should exist documenting that all occupants, such as employees, residents, customers or visitors, respect additional rules about budgetary issues, privacy, using drugs or alcohol, and other expectations. To this end, whether there is a pertinent training program or not, and further whether its results meet the minimum expectations of security or not, should be documented. It is crucial to reinforce and promote a sentiment of "security culture," particularly in a diverse and crowded urban environment. It is crucial to create, establish, and preserve a culture of security, especially with so many and different tenants within a so complicated environment of the metropolitan area (Garcia 2006).

Furthermore, the socioeconomic and political environment, regulatory requirements and legal issues are to be considered when protecting public spaces. The security expert must be in a position to critically think about what policies and laws are applicable for all tenant organizations and the facility as a whole, either as a mandate or in order to increase security. Also, the knowledge of previous history regarding privacy, labor relations, training of guards and tenants, criminal statistics, and other legal issues are critical to reduce liability as a result of an overreaction or failure to protect. This corpus of knowledge must not be outside of safety considerations. Security experts must meet and collaborate with facility managers or other persons who are responsible for safety. Although security and safety may have different goals, they are considered complimentary functions. The term "integrated solutions" is used to project this desire and culture for coexistence of security and safety issues (Garcia 2006).

Finally, whether an employee of the facility or not, the security expert must partner in the strategic plan of senior management of all organizations residing in the high-rise building. Respecting their policies and issues of privacy, the security manager must know the potential threats, assets, and vulnerabilities of each and every occupant organization. Also, if necessary, mutual aid agreements with other organizations or industries should be at expert's discretion after consultation with C-suite level of management. That said, a security manager must be extrovert and develop relations with other facilities and identify who is the liaison between the facility and local law enforcement (Garcia 2006).

Focusing on "physical security," the following goals for security countermeasures are suggested for public places. There are three main goals for all security countermeasures (Norman 2015): (a) where possible, identify and deny access to potential threat actors; (b) deny access to weapons, explosives, and dangerous chemicals to the facility (except for legitimate exceptions, which should be well controlled and monitored); and (c) make the environment suitable for appropriate behavior, unsuitable for inappropriate or criminal or terroristic behavior, and mitigate the actions of both hazards and threats.

> [P]ractically, these goals are achievable mainly through specific functions, which are: "access control"; "deterrence"; "detection"; "assessment"; "response (including delay)"; and "evidence gathering", among others. Of particular importance are detection of an adversary, delay of that adversary, and response by security personnel, using hi-tech, lo-tech, and no-tech countermeasures. (Norman 2015)

Prior to designing a physical protection system, it is crucial to set the objectives, or simply state what to protect and against whom. Moreover, beginning with the designing of the system, the integration of people, procedures, and equipment is necessary in order to meet these objectives. At the same time, designing should consider issues regarding safety, as well regulatory, operational, legal, and economic limitations (Garcia 2006).

Furthermore, information should be obtained about the type of facility to be protected, which in turn will show the level of protection needed based on the percentage of publicly owned space. For instance, the security management professional should clarify whether a facility is public, or part of the facility is public, though privately owned. In doing so, one may understand potential private ownership constraints, which in turn may affect the overall security operations and performance. Second, identifying and defining threats for the facility is of the utmost importance, a process which needs effort and time. A threat definition is a detailed description of the physical threat by a malevolent adversary to the system. In addition to that, the concept of design basis threat (DBT) of the facility should be established in order to facilitate decision-making and establish technical requirements for security of the facility (Garcia 2006). For public spaces, certain threats, such as crimes or active-shooting situations, may harm public safety and impact on social and economic life. Finally, it is of the utmost importance to consider all as discussed above, in order to adopt risk mitigation strategies by improving the capacity to manage organizational risk of facilities in public spaces.

Public spaces that are considered "soft targets" for crime and terrorism require special consideration. *Soft targets* include locations difficult to

defend or usually undefended, typically non-governmental sites – and oftentimes places where people congregate in large numbers – as well as targets of some other value (e.g., national monuments, hospitals, schools, sporting arenas) (Robbins 2006). Typical acts of terrorism perpetrated against soft targets are attacks to public transportation, such as the 2004 series of coordinated explosions on commuter trains in Madrid, which killed 191 and wounded over 2000, and the July 2005 terrorist attacks in London, whereby four perpetrators carried out coordinated suicide bombings on a bus and three subway cars in London, killing 52 people (Law 2009). These and other public spaces are particularly challenging to secure. Nevertheless, soft targets may be "hardened" by adding layers of defense. Defensive measures aim to deter and with respect to public spaces are the following: barriers; surveillance' checkpoints; ID protocols; establishing of choke points for people or traffic flow; and restricting vehicle access to buildings or areas near them (Robbins 2006). The use of technology (e.g., CCTV) in such public areas contributes to creating a sense of security in all occupants (employees, residents, customers, or visitors) (Wakefield 2003).

Additional Practical Considerations for Establishing Public Safety

Security management experts may face security, safety, or both types of challenges, when evaluating or installing relevant devices in non-private facilities or assets, either open or not. Consequently, they should have in-depth knowledge of the functions of security and safety. In fact, a security expert or a security-oriented organization (either public or private) is called to identify and deal with any potential threats that are either security-driven or safety-driven threats.

It is expected that the security management expert is (or the team of experts are) knowledgeable of state-of-the-art security and/or (fire) (life) safety systems that are in compliance with policies and laws, as well as experienced in conducting security and/or safety surveys, particularly in public spaces. For instance, security countermeasures for accessibility should be in compliance with Americans with Disabilities Act (ADA), which is applicable to businesses and other organizations that operate places of public accommodation (i.e., restaurants, theaters, transportation facilities, retail stores, doctors' and lawyers' offices, private schools, day care centers, libraries, and hospitality facilities) (Atlas 2013). Moreover, the experts may have certain professional qualifications that would qualify them to be called to make or implement recommendations or in the event of future litigation to testify on behalf of the building owner or operator (Craighead 2009). Last but not least, such experts should have a well-established professional relationship with local law enforcement or fire authorities having jurisdiction.

A security formula is recommended for protection management experts that incorporates the a "Crime Prevention Through Environmental Design" (CPTED) concept into security ordinances, resolutions, and guidelines. "[A]ccording to the Defensible Space Theory, CPTED takes advantage of the practical considerations of "territoriality", which essentially means to reassign the physical areas of a space, which in turn will enhance local people to better control the environment and in particular public spaces. . .Territoriality can be accomplished by using a hierarchy of space as defined in Defensible Space Theory, such as subdividing public spaces into semi-public and semi-private places" (Atlas 2013). Elaborating on the "Crime Prevention Through Environmental Design" (CPTED) concept, a design is proper if it recognizes the designated use of the space; defines the crime problem incidental to and the solution compatible with the designated use; and incorporates the appropriate crime prevention strategy that enhances the effective use of space (Atlas 2013).

Conclusion

Security is becoming a greater priority in the design, construction, operations, and management of buildings and facilities.

Port security · Port threats · Public-private partnerships · Information sharing · Critical infrastructure · Supply chain · Security networks

P

Definition

Port security refers to security and law enforcement measures employed to safeguard port assets (vessels, harbors, facilities, cargos, employees, visitors) from natural and man-made threats, as well as from criminal activities.

Introduction

The security of maritime transportation is essential for the international economic well-being and as such is one of the subsectors in the critical

infrastructure. Critical infrastructure refers to a vital system that performs a specific function in society, "whose cessation or destruction would have a significant impact" (Curt and Tacnet 2018, p. 2441). According to the United Nations Conference on Trade and Development (2017), 80% of global trade by volume and more than 70% by value is carried on ships and handled by seaports worldwide (p. 61). Mega ports across Asia, North America, and Europe provide the primary maritime system for most of the world. Maritime shipping, like other transportation systems, faces several challenges in establishing and maintaining the access controls needed to secure shipments near a port, in port, or in transit from a port (Purpura 2008). In particular, ports must facilitate legitimate trade while at the same time protecting their assets against a myriad of threats.

Challenges in meeting the security needs of ships stem from two interconnected sources. First, the public and private sectors are responsible for monitoring the large volume of cargo transported internationally by ships. Second, in order to make a profit, this cargo must be transported quickly and efficiently. Even though ports are more secure today, they are still vulnerable due to their economic importance, the speed of shipping, and their visibility, and despite the maritime sector's vulnerability to natural and man-made threats, it has not received the same attention as other transportation sectors, due primarily to the small number of security incidents that have been made public.

After 2001, the maritime support system, including its ports and ships on the ocean, was determined to be a particularly attractive target because of its importance to the global supply chain of goods, its vulnerability due to gaps in security, and its strategic importance (Mat Salley 2006). Governments, law enforcement, intelligence agencies, and the private sectors of many nations realized that new threats to the maritime transportation mode were evolving at a rapid pace. For example, Bowley (2013) argues that a significant attack on one or more of the large mega-ports capable of servicing large vessels could cause substantial disruptions to international trade by impacting the current "just-in-time" business principle. The possibility of losing access to even one major port for several days would be highly problematic for the USA as it would affect not only the local area, private businesses locally and abroad but also the federal government (Government Accountability Office 2007).

The United States' borders include not only the southern border with Mexico and the northern border with Canada but also different areas of liquid borders between ports of entry in the Great Lakes as well as along the Pacific and the Atlantic oceans (Subcommittee on Border and Maritime Security 2011). The U.S. Coast Guard (USCG) is responsible for securing these borders, stopping drug trafficking, and performing other essential missions. The maritime system, however, is global and requires transnational cooperation to secure it against various threats – the U.S. Customs and Border Protection currently has 54 memorandum of understanding (MOU) with multiple partners (Government Accountability Office 2018). Meeting these threats is possible only through public and private partnerships (PPP) as neither public nor private entities fully control security at ports. Specifically, both the public and private sectors must work together "to establish a common scope, objectives and a working methodology to achieve shared goals" (The International Centre for the Prevention of Crime 2018, p. 141).

Port Security

Ports are both unique and complex as they often involve government-owned operations, private terminal operators, and other organizations that lease port authority facilities. This variety of ownership makes security complicated. As Brewer (2014) argues, the public and private "nodes" of each of these infrastructures have distinct interests, duties, responsibilities, and powers in policing the waterfront and the port. Traditional methods of crime prevention are not well suited to this context and a collaborative approach involving police, governments, and the private sector is necessary. Effective public-private sector coordination is vital to achieving resilience in maritime port security (Busch and Givens 2014).

Port Threats

In the modern era, traditional port crimes such as smuggling, piracy, and theft have been joined by other types of offenses – sabotage, labor unrest, insider threat, cyber-threat, stowaways, tampering with shipping containers, and leaving a dangerous item on a dock, as well as smuggling a weapon of mass destruction and other forms of terrorist acts (Brewer 2014; Christopher 2015; Government Accountability Office 2016; McNicholas 2016; Washington Post 2014). According to Fennelly et al. (2017), because most of the global trade consists of raw materials, controlled products, food, automobiles, clothing, and electronics, moving it by sea is the most effective way to proceed. However, this mode of transport relies on high volume, which creates challenges for the governments and private organizations responsible for ensuring safe and secure cargo. For instance, in the USA, only about 4% of cargos are inspected at seaports, while in Canada, it is only 2% (Quigley et al. 2017). This low percentage of inspection creates a major vulnerability for organized crime to exploit.

As an examination of all threats is beyond the scope of this chapter, only four of the threats seaports are currently facing are further examined here – terrorist threats, natural threats, insider threats, and cyber-threats. While terrorist and natural threats to maritime and port security have been discussed in the literature, cyber- and insider-threats are relatively new threats to law enforcement and must be carefully considered by port security management.

Terrorist and Natural Threats

Since 9/11, the threat of terrorism has forced ports to invest considerable amounts of money in security measures. However, although the probability of problems due to natural disasters and climate change is greater than the threat of terrorism such as the use of explosives or bombs to generate fear among the population, ports are not as prepared as they should be to maintain their operations when faced with such challenges. The Coast Guard is accustomed to guarding against cargo theft, drug smuggling, human trafficking, and stowaways. However, port security management teams and their law enforcement partners must also have emergency management and response plans in place to protect people and facilities from future natural threats as well as terrorism (Maritime Executive 2011).

Climate change will be a significant natural threat to ports in the future as changes in water level, storms, precipitation, and higher temperatures are likely to affect them directly (U.S. Environmental Protection Agency 2008). Threats from hurricanes include high winds, heavy rainfall, storm surge, coastal and inland flooding, and rip currents, as well as tornadoes – the 2005 hurricane season, which included Katrina, Rita, and Wilma – was particularly challenging for ports (Government Accountability Office 2007). It is already clear that natural events not only cause loss of life but also have a significant economic impact on ports – the total cost of damages for the Port Authority of New York and New Jersey from Hurricane Sandy in 2012 has been estimated at US$ 2.2 billion (Quigley et al. 2017). On a positive note, when hurricane Maria hit Puerto Rico in 2017, port operations were more resilient in maintaining functional operations, evaluating cargo shipments, and scanning incoming containerized cargos (Odegaard 2018). After only 36 h, the port operation was back to normal operations (Odegaard 2018).

Communication, interpersonal coordination, and interagency coordination are the three most common problems during natural disasters (Government Accountability Office 2007). Two best practices to ensure people know what to do and how to react to a natural or man-made crisis are having updated emergency management plans and conducting tabletop exercises to practice emergency situations with stakeholders to assess the ability of different government agencies and business entities to respond to and recover from a crisis (U.S. Department of Homeland Security 2005).

Cyber-Threats

Effective information and communications technology are vital to protecting maritime and port

infrastructure (Willis 2016). Logistics systems rely on technology to monitor the flow of shipments as well as transactions among manufacturers, carriers, and shipping organizations. Vessel navigation depends on the global positioning system and automated control systems are now an important part of the port infrastructure, for example, in shipment navigation, natural gas transportation, oil loading or unloading, and electric grids. However, the technologies that increase efficiency in maritime transportation also heighten the system's vulnerability to cyberattacks as these systems can be exploited to disrupt port operations or to damage port infrastructure (Willis 2016). Navigation or control systems can be hacked, increasing the risk of vessel collisions, and the integrity of data control systems can be compromised so that manifest information cannot be trusted (Willis 2016). Some examples of cyber-threats for ports are the risk of having a cyberattack against servers, phishing and spear-phishing attacks, zero-day exploits, or man-in-the-middle (session hijacking) attacks among others.

Besides, according to the International Maritime Bureau (IMB), there is a real danger that emails being sent to and from ships are monitored or altered, thus potentially affecting commercial transactions. Many vessels are still using outdated computer software that has not been designed with cybersecurity in mind, exposing ships to cyberattacks (Bull 2016). Willis (2016) questions whether the current protection and redundancies in place to mitigate these vulnerabilities are sufficient, and if it is clear, who is to respond to any cyberattack on port infrastructure in the future.

Cyberattacks on the maritime transportation system can result in loss of life, physical damage to critical infrastructure, disruption of supply chains, and theft of sensitive information, as well as being used to support criminal organization activities such as cargo smuggling or cargo theft (Transport Canada 2016). In June 2017, Maersk, the world largest container shipping company was the victim of a cyberattack that demonstrated the scale of damage a computer virus can create in an interdependent and interconnected industry (Saul 2017). This cyberattack was the most critical disruption of the global shipping industry to date as several ports operated by Maersk in the USA, India, Spain, and the Netherlands were unable to conduct business. The company was forced to shut down its computer systems to carry out a forensic investigation, which meant that, since the global positioning systems were not functioning, it no longer knew where its containers were, increasing the possibility of further loss and/or theft (Saul 2017).

To prevent a similar situation, shipping companies should conduct joint cybersecurity vulnerability assessments with law enforcement to assess their computer systems and evaluate the risk of any type of cyber-related attacks. Companies should have an updated recovery plan and governance and oversight of their security programs should be implemented by a cybersecurity committee, which should also review their access controls and computer network design, updating (or installing) an intrusion detection system and securing all communications through encryption (Transport Canada 2016).

Insider Threat

Managing and detecting employees at risk of committing internal criminal conspiracies is a complex challenge for seaports (Christopher 2015). Catrantzos (2012) defines an insider threat as "an individual and, more broadly, the danger posed by an individual who possesses legitimate access and occupies a position of trust in or with the infrastructure being targeted" (p. 4). Port employees may help members of organized crime groups to smuggle drugs or instruments of terror as part of legitimate cargo traveling on commercial vessels and cruise ships or may remove contraband material or conceal it before it can be detected by U.S. Customs and Border Protection or technological detection systems (Christopher 2015). When using cargos as a mean to transport drugs, organized crime almost always relies on the assistance from port employees. In 2018, authorities working at the Port of Rotterdam in the Netherlands and the Port of Antwerp in Belgium seized more than 73 metric tons of cocaine, a 35% increase from

the year before (Den Held and Asmann 2019). According to Den Held and Asmann (2019), corrupt workers at the Port of Antwerp earned between EUR 75,000 and EUR 125,000 per drug shipment.

Those who pose an insider threat may have other motives, such as helping to launch cyber- or physical-security attacks on the maritime global supply chain (Shapiro et al. 2018). Ports and naval employees may also be interested in aiding state or non-state actors who want to disrupt national security or critical infrastructure operations either for personal economic gain or to lead to a loss of revenue for private and public organizations (Shapiro et al. 2018). A recent risk is the threat of homegrown violent extremism (Cozine 2019). For example, a radicalized employee working at a port or a visitor of the port could be a threat to the security of the port operations, the safety of employees, and assets in the event that a terrorist attack would be perpetrated in a port area. Screening employees and visitors through background checks is key in risk management. Being able to identify individuals who show signs of radicalization or extremist behaviors and characteristics is also essential for law enforcement professionals working at ports (see chapter on ▶ "Border Security" in this volume).

The Importance of the Supply Chain

Most criminal activities carried out by transnational criminal organizations using ships and containers to exploit vulnerabilities within the maritime supply chain are very lucrative. On average, 675 shipping containers are lost or stolen at sea each year, which has substantial consequences for the finances and reputations of private organizations (World Shipping Council 2017).

Fennelly et al. (2017) argue that supply chain security in the future will be tied to what they refer to as the sea lines of communications (SLOCs) which, as the focus of maritime security, will affect ports, shipping lanes, chokepoints, and coastal waters as the ability to move goods quickly and securely will continue to be paramount for global commerce. SLOCs will bring about a shift in regulations, with an emphasis on supply chain and cargo security leading to a change in the present focus on port security. This systemic approach will be possible due to significant developments in technology that will provide improved methods of tracking, smart locks, and information databases, allowing cargo to move through the supply chain quickly, securely, and efficiently. It will also make it possible to identify cargo loads operating outside the regular security pipelines (Fennelly et al. 2017). To comply with federal regulations and controls, shipping companies will rely on specialized examinations and testing to certify cargo ships before they sail (O'Brien 2015).

Law Enforcement Initiatives

Different strategic initiatives to improve security and share intelligence have been implemented over the years. The Shiprider program is an excellent example of work that is being done across the US/Canadian border with the assistance of the Royal Canadian Mounted Police (RCMP), as is the integrated 2006 Cross-borders Maritime Law Enforcement Operations (ICMLEO, Royal Canadian Mounted Police 2016). The Coast Guard's Deployable Operations Group illustrates the role that maritime, port security, and specialized naval teams play in the Coast Guard's post 9/11 mission. This group was created in 2007 as a domestic maritime counter- and anti-terrorism force against threats at home and abroad and brings together organizations such as port security, tactical law enforcement teams, maritime safety units, and security response teams (Subcommittee on Border and Maritime Security 2011; Lowe 2016). For example, this group was deployed for the 2010 earthquake in Haiti and in the piracy mission of the 2009 Maersk Alabama hijacking case on the African coast (Lowe 2016).

Public-Private Partnership Initiatives

Many initiatives have been undertaken by public and private partners to enhance port and maritime

security. The Container Security Initiative (CSI) that examines high-risk, US bound, containerized cargos at foreign ports, the 24-h rule that requires that freight manifests be submitted at least 1 day before shipment arrivals, and the 96-h rule (prior to arrival) for ships bound for US maritime ports are excellent examples of initiatives aimed at protecting ports and increasing maritime security (Busch and Givens 2014; Christopher 2015). The Coast Guard has worked with Microsoft to produce an electronic chip that allows ship's crews to enter information in computers while they are at sea and offline and then transmit this data to the Coast Guard. As such, it keeps the Coast Guard informed of the ships' positions at sea once they have access to the Internet, increasing the efficiency of security operations and the productivity of crew members (Busch and Givens 2014).

The Customs-Trade Partnership Against Terrorism (C-TPAT) initiative, which works voluntarily with the Customs and Border Protection agency to undertake inspections for US importers, is another example of a partnership that has increased transparency in the supply chain, helping to identify suspicious shipments (Government Accountability Office 2016; Maritime Executive 2011). The Transportation Worker Identification Card program helps screen employees and individuals who have access to critical port infrastructure (Willis 2016), and the X-ray, gamma-ray, and radiation detection systems at ports have contributed to reducing the risk that different types of bombs and radiological materials will be shipped in inbound cargo containers (Maritime Executive 2011; Willis 2016).

Another example of an excellent public and private partnership initiative is the creation of the Maritime Security Council, which developed an Information Sharing and Analysis Center (ISAC) composed of public and private actors representing maritime port employees from around the world. Representatives from both sectors work alongside each other, fostering collaborations that produce information essential to decision-making. This type of PPP initiative or fusion center facilitates information-sharing between maritime port security stakeholders such as the U.S. Coast Guard and various private entities (Busch and Givens 2014). In their study of Australian fusion centers, Bright and Whelan (2018) argue that the "hub-and-spoke" model should be prioritized in sharing information for national security and law enforcement purposes. This model has a primary center that acts as a central "hub," while various Joint Analyst Groups (JAGS) – multiagency groups located in major jurisdictions or regional fusion centers – are connected to the central hub (Bright and Whelan 2018).

As it is common in the protection initiatives of different industries and with regard to critical infrastructure, port security professionals should use data analytics techniques, such as machine learning, to identify possible common denominators, suspicious activities, or anomalies in employee's behaviors to detect potential insider threat as well as any potential criminal activities (see chapter on ▶ "Machine Learning" in this volume). Data is critical in managing security, and data analytics for port security is no different than that dealing with other critical assets. Data analytics techniques make it possible to learn continually from port security data by focusing primarily on high-risk behaviors and anomalies while prioritizing financial resources, efforts, and costs in mitigating port security risks, as well as using data sets to create rules and models that reduce false positives. Security analysts should rely on real-time data that allow them to create a detailed threat assessment by pulling relevant and valuable data from multiple sources (e.g., scanning data, employee data, information logs, security logs), making it possible to conduct targeted and risk-based security assessments (Odegaard 2018). The use of data analytics should be explored further to understand how it can be used to manage various threats, such as those posed by gaps in cybersecurity or criminal insiders, and to improve port security.

How Private and Public Partnerships Could Improve Port Security Going Forward

Various modes of crime controls and incidents may be part of the future of maritime

transportation (Brewer 2014). To increase efficiency, the traditional and rigid hierarchical structure presently used to manage security needs to be replaced by a horizontal structure that is more flexible, fluid, and adaptable to the level of complexity now found in criminal organizations (Cozine et al. 2014; Gerspacher and Dupont 2007). New legislation may be necessary to allow law enforcement and public entities to work more closely with the private sector. For example, the public sector has the power to enforce the law, but the private sector has access to an enormous quantity of data that is needed to prevent crime and terrorism. The private sector also has skills and financial and human resources that the public sector lacks. Private sector professionals with skills in data analytics, computer science, or cybersecurity should be leveraged to improve the overall security of ports by combining their work with the strengths and knowledge of the public sector.

The flexible networks now being used by organized crime and terrorist groups give them a competitive edge (Gerspacher and Dupont 2007). A horizontal organization in port security would promote increasing trust between member organizations, encouraging better information-sharing capabilities and lower operating costs than the conventional vertical integrated structures used by most agencies and private companies today (Dupont 2015). Trust between public and private organizations is critical to trans-governmental cooperation and to meet cross-jurisdictional challenges such as combating terrorism and transnational crime (Cozine et al. 2014).

As argued by Dupont (2015), legitimate networks will have to adopt and mirror the structure of organized crime networks if they hope to be successful in countering their actions. These future networked systems will have to build layers of protection and defense-in-depth structures if they are to deal effectively with critical system security risks while preserving flexibility, functionality, and efficiency (U.S. Department of Homeland Security 2005).

Future security networks will also need to emphasize the importance of cooperation and participation between both domestic and international stakeholders as well as making sure that each partner uses their expertise to manage strategic points (U.S. Department of Homeland Security 2005). According to Brewer (2014), protecting ports from crime and natural disasters will require mobilizing public and private actors in highly connected security networks that demonstrate trust in their peers, build social capital, and engage in activities of co-production towards the same common objectives. More specifically, networks of public and private actors could work together to plan joint investment projects in digital technology as well as employee training (e.g., protection techniques, vulnerability assessment). The same networks should also collaborate in audits and inspections and in creating new standards for port security when responding to man-made and natural crises, as well as co-creating new types of technological security software and hardware to improve port and maritime security.

The private sector might take the lead in providing security and video surveillance at ports, which would allow the public sector to allocate more resources to other priorities for port and maritime security. The private sector could also bring new security skills, such as techniques like crime prevention through environmental design (CPTED), to enhance physical security and access controls while the public sector would continue to be responsible for enforcing the law.

The private sector could assist public sector port authorities in using data analytics to improve their intelligence, enabling them to better detect insider threats, as well as with computer science and encryption skills that would help them work with law enforcement to mitigate cybersecurity threats to ports, communications, cargos, and vessels. Increased intelligence would also facilitate crucial decisions such as the deployment of personnel and the use of automated processes (Odegaard 2018).

Furthermore, if intelligence is accumulated in a fusion center such as an ISAC, data can be gathered in one platform, aggregated, analyzed, and more easily disseminated to the right individuals. This approach would enhance collaboration in using data from both internal and external services to create an optimal intelligence

cycle for public-private partnership security networks (Odegaard 2018). Finally, the private sector might also assist in improving security at ports by developing innovative biometric capabilities as well as the use of satellite imagery or unmanned aerial vehicles.

Conclusion

The digital evolution of our globalized economy will continue to progress and change rapidly. This progress will bring more challenges and new risks. Cybersecurity and insider threat risks will significantly increase the economic and national security challenges for ports and maritime security as well as other critical infrastructures. Adversaries will employ different sophisticated technological tools and substantial financial resources to achieve their criminal goals. Like governments, the private sector and public law enforcement will have to adapt and deal with these threats in a context of limited resources. It will thus be imperative for security and law enforcement professionals to use a risk-based approach in making decisions and choosing strategies as prevention measures and technological controls are extremely expensive to deploy, difficult to implement, and to maintain.

Crime-control partnerships between public and private actors have often been implemented to provide physical security and access control, and the same approach must be taken to manage cyber and technological threats. Digital networks using secure online communications to share intelligence about threats towards ports should be given priority. Moreover, governments should continue to encourage the private sector to design security hardware and software that promotes security (Yang 2010). The efficiency of public-private partnerships should be quantified through evaluation plans that assess the overall performance of such partnerships based on measurable objectives, key performance indicators, and evaluation methodologies, which will facilitate the implementation of future partnership programs (Government Accountability Office 2018).

The security measures established since 2001 through public and private partnerships and new legislation have improved port security while maintaining port efficiency (Willis 2016), but ports are still significant targets for man-made and natural threats, and there are still challenges in information sharing. More emphasis should be given to protecting national security, the economy, and people. To succeed in this strategic objective, partnerships between various public and private actors will be vital to mitigating future risks.

Public-Private Partnerships: Security Organizations

Christopher Cleary
St. John's University, New York, NY, USA

Keywords
NYPD Shield · FBI InfraGard

Definition

Public-private partnership (PPP) information sharing networks are communication networks that enable the flow of security and threat information between public sector law enforcement agencies and private sector businesses. The networks are mutually beneficial efforts combining the resources of all participating entities to provide a unified and coordinated defense against potential hazards and threats.

Introduction

Security professionals must guard against a long and evolving list of potential threats and hazards. Some security problems such as theft, unlawful violence, and natural disasters have been present throughout recorded history. Other serious problems such as cyberthreats have recently emerged but pose significant security challenges.

Providing protection against all potential natural, accidental, and intentional threats and dangers cannot be accomplished by any single private or governmental entity. Combining the resources of both sectors has proved to be a mutually beneficial method to enhance capabilities. In their report on information sharing, the Department of Justice recognized the need to collaborate, saying, ". . .neither law enforcement nor private security can protect the nation's infrastructure alone, law enforcement-private security partnerships are essential to bridging the gap" (US Department of Justice 2005).

Public sector law enforcement agencies referenced in this paper include federal, state, tribal, and local entities that provide policing or investigative services. It is estimated that there are over 18,000 state and local law enforcement agencies in the USA employing more than 600,000 sworn members (US Department of Justice 2016).

Private sector entities referenced in this paper include for-profit and not-for-profit corporations, businesses, agencies, and organizations. The security for these entities may be the responsibility of:

- A commercial security firm contracted to provide security to a private entity.
- A security specialist employed by a private entity to improve security and disaster planning.
- A business owner or employee who is not a security specialist but has the responsibility for security and disaster planning.

It is estimated that there are over 1.1 million private security officers in the USA (US Department of Labor 2017). The total number of individuals involved in security-related decision-making in the US private sector is unknown but can be assumed to be higher.

The resources from both the public and private sectors that are tasked with preventing crime and maintaining homeland security are significant, but collaboration greatly increases their effectiveness. There has been increase in collaboration through the implementation of information-sharing networks designed to safeguard cyber networks and critical infrastructure locations and to protect against acts of terrorism.

Collaboration

Private sector entities provide for the security of their physical property and proprietary assets but rely on public sector services to fill gaps that are beyond their abilities. Private sector security might lawfully detain a subject for committing a trespass upon their company property but rely on local police and the district attorney to process the arrest and prosecute the offender. Public sector agencies are limited by having finite resources that are insufficient to provide comprehensive security for every potential target of illegal activity or disaster within their jurisdiction. State, tribal, and local police agencies provide general patrol coverage within their jurisdiction but don't have the staffing necessary to post police officers at every critical location, such as facilities operated by small businesses, electric power utilities, drinking water providers, communications companies, or the financial sector. Public sector entities must rely upon the private sector to provide specialized equipment and expertise that may not be available in the public sector, as well as in-depth knowledge of their proprietary locations.

While public and private entities develop their individual plans to increase preparedness and resilience, the plans are likely incomplete unless they include cooperation agreements or understandings with other entities to fill in gaps. Individual plans must be coordinated with other agencies or entities that are expected to play a role in the plan (Federal Emergency Management Agency 2010, pp. 1–7). Collaboration is a key component to developing a comprehensive security plan.

After the terror attacks of September 11, 2001, information sharing was recognized as a key component of cooperative collaboration to defend the nation against acts of international terrorism. In their Final Report, the 9/11 Commission noted:

> ". . .the private sector controls 85 percent of the critical infrastructure of the nation. Indeed, unless a terrorist's target is a military or other secure government facility, the "first" first responders will almost certainly be civilians. Homeland Security and national preparedness therefore often begins with the private sector." The commission further noted that "Private-sector preparedness is not a luxury; it is a cost of doing business in the post-9/11 world. It is ignored at a tremendous potential cost in lives, money, and national security." (9/11 Commission 2004, p. 397)

Information Sharing

Many criminal justice agencies at the federal, state, and local levels recognized the importance of sharing information across jurisdictions and

across disciplines to develop a common operational picture. Public sector law enforcement agencies have access to the most current intelligence which is needed by, but may be inaccessible to, private sector security providers. Private sector entities have in-depth knowledge and expertise of their own industry and their own facilities. Private sector entities will also have knowledge about suspicious activities that do not reach a reporting threshold but would be of interest to law enforcement, such as irregular purchases of components used to construct improvised explosive devices like commercial fertilizer or concentrated peroxide.

The National Criminal Intelligence Sharing Plan provides policy recommendations for criminal justice agencies to establish information sharing as an essential function of policing strategy and states "Law enforcement agencies should consider creating and implementing outreach strategies in order to develop and enhance partnerships with the private sector, nonlaw enforcement public safety disciplines, privacy advocates, and community groups" (US Department of Justice 2013, p. 17).

While there are many benefits to participation in a public-private network, sharing information between public and private entities is a complex problem. Sharing data that was collected by the US intelligence community has the potential to expose, and thereby render ineffective, valuable collection capabilities or assets, including the ability to intercept electronic communications, or human intelligence assets (covert operatives and confidential informants). Information or data collected by covert collection methods that has been processed and analyzed into intelligence products will likely be designated Classified National Security Information, which prevents its dissemination to anyone without a government issued security clearance (Executive Office of the President 2009). A large percentage of the information held by law enforcement agencies relates to criminal cases, the release of which would likely make further investigation and prosecution of the cases difficult or impossible. Additionally, criminal justice agencies often possess sensitive information about citizens (identification of crime victims, medical or psychiatric records) which should not be divulged without legal authorization.

Private companies face serious issues of trust, control, and disclosure while deciding whether to share information with the public sector. Sharing information about a criminal occurrence, such as a cyber intrusion, might result in the company losing control of their own investigation or of sensitive proprietary information being made public. Even though a cyber intrusion might cause serious damage, the company might decide that reporting the intrusion might result in greater damage to the company's image or reputation (Hernandez 2017).

To encourage the private sector to share sensitive information, many PPP networks utilize privacy protection guidelines. The Traffic Light Protocol (TLP) is one example of a privacy protection guideline. TLP uses a four-color system to help ensure that proprietary or sensitive information is only shared with the "proper audience." Sources may use:

- TLP: Red when dissemination of the information could cause damage to an entity's privacy, reputation, or operation, and it cannot be acted upon by other entities.
- TLP: Amber can be used when dissemination of the information could cause damage to an entity's privacy, reputation, or operation, but requires support to be acted upon.
- TLP: Green can be used when the information could be useful if disseminated to all partner organizations within the sector or network.
- TLP: White can be used to identify information that can be disseminated freely with little or no foreseeable negative effect (US Department of Homeland Security 2016a, p. 14).

Critical Infrastructure Protection

In 2013, a Presidential Policy Directive identified 16 critical infrastructure sectors which are "systems and assets, whether physical or virtual, so vital to the United States that the incapacity or destruction of such systems and assets would have

a debilitating impact on security, national economic security, national public health or safety, or any combination of those matters" (Executive Office of the President 2013, p. 12).

The federally designated critical infrastructure sectors include the chemicals, commercial facilities, communications, critical manufacturing, dams, defense industrial base, emergency services, energy, financial services, food and agriculture, government facilities, healthcare and public health, information technology, nuclear reactors, materials as well as waste, transportation systems, and water and wastewater systems (Executive Order No. PPD-21 2013).

The FBI instituted the *InfraGard* network to facilitate the exchange of all-hazards information between the federal government and private sector agencies to protect the nation's critical infrastructure from acts of terrorism and other criminal activities. The InfraGard network was initiated in 1996 in the Cleveland Field Office and has grown into an alliance of 82 local chapters throughout the USA. Each chapter is composed of businesses, state, tribal, and local law enforcement agencies, and academic institutions controlled by a locally elected board of directors that ensures their specific information-sharing needs are met.

The goals of the InfraGard program are to:

- Improve communication and reporting between the FBI and InfraGard partners related to major crimes, cybercrimes, and hostile acts against the USA or US interests.
- Facilitate the quick dissemination of relevant threat advisories, alerts, and warnings.
- Increase liaison and sharing of information on threats with critical infrastructure and key resources providers and their interdependencies.
- Provide training and education opportunities for members on counterterrorism, counterintelligence, cybercrime, and other issues relevant to security and resilience.

To ensure the security of the information being shared, the FBI conducts a vetting investigation on prospective members. Once the investigation is completed, participants are permitted access to the secure members-only InfraGard website, which contains intelligence and informational products and publications and provides a pathway for members to provide notifications of suspicious activity back to the FBI for investigation or for informational purposes.

(Federal Bureau of Investigation 2018).

Counterterrorism Networks

The threat of terrorism continues to be one of the most serious challenges faced by security providers. The threat comes from individuals who are either directed to commit atrocities by a terror organization or by individuals acting on their own who have been inspired by a terroristic ideology. Security threats are posed by both foreign terror organizations and domestic extremist groups (Federal Bureau of Investigation 2017).

NYPD Shield is a web-based information-sharing network of police, first responder agencies, and private sector security providers that is primarily focused on sharing threat information to guard against acts of terror within the New York City region. Controlled and operated by the New York Police Department (NYPD) Counterterrorism Bureau, the network was created with the understanding that defending against terrorism is a shared responsibility that requires the active participation of both public and private sector agencies.

NYPD actively solicits participation from private sector agencies, businesses, and corporations. Potential members undergo a vetting process designed to protect the integrity of the network. Once approved, members are encouraged to use the network and the information provided therein to bolster their entities' security against and resilience to acts of terrorism and to act as a force multiplier in recognizing and reporting suspicious behavior.

The successful Shield program was awarded the Michael Shanahan Award for Leadership in Public/Private Cooperation by the International Association of Chiefs of Police and the Security Industry Association (International Association of Chiefs of Police 2015).

Members of the NYPD Shield network participants are provided with a variety of products and services related to preparedness and security including (New York Police Department 2018):

- Briefs and analyses of security issues related to upcoming special events, mass gathering locations, critical incidents, and acts of terror from around the world,
- Security-related guides and publications produced by NYPD on topics include recommendations for active shooter protocols, security recommendations for high-risk buildings, and in-depth analysis of terror groups,
- The weekly terrorism brief contains an overview of each week's most relevant incidents, trends, and policy issues related to domestic, homegrown, and international terrorism. The brief also highlights topical issues of global security which are not directly tied to terrorism.
- The CBRN weekly brief contains assessment of open-source incidents related to chemical, biological, radiological, and nuclear incidents and security.
- Corporate and private sector training, which is available on request to participating member organizations. The NYPD counterterrorism bureau provides training courses that are available on request and cover topics including terrorism awareness, suspicious mail and packages, vehicle-borne improvised explosive device checkpoints, and critical infrastructure protection.
- A resource library with links to information on best practices and safety and security recommendations regarding all-hazard threats for general and sector-specific users,
- Shield conferences, which are held periodically to provide members with presentations from subject matter experts discussing issues and incidents related to terrorism.

Cybersecurity Networks

Cybercrime has become one of the most predominant and dangerous threats to security. A cyberattack can result in valuable data to be stolen, destroyed, or held for ransom. Sophisticated intrusions have been perpetrated by foreign governments, criminal organizations, professional hackers, hacktivists, and terrorist organizations. According to the FBI, cyber intrusions intending to illegally access and steal classified information, trade secrets, technology, and ideas are continual and growing problem. Hackers are also constantly attempting to access and attack critical infrastructure which could cause significant harm to our economy (Federal Bureau of Investigation 2017).

Cybersecurity is an area that benefits greatly from combining resources through public-private partnerships. Many private sector entities use sophisticated and specialized methods to detect and prevent intrusions. The public sector is authorized to investigate cybercrimes and, when necessary, work with international agencies to develop intelligence about the cyberthreats (Hernandez 2017).

Since cybercrime has the potential to affect almost every aspect of security, most PPP information-sharing networks, regardless of their primary focus, share information on cyberthreats. However, there are networks solely dedicated to the protection of cyber assets. The Department of Homeland Security (DHS) is the lead federal department for protecting "whole-of-nation" critical infrastructure, including cyber assets and has developed and implemented numerous information-sharing programs designed to enhance network security:

- The National Cybersecurity and communications integration center (NCCIC) is designed to create shared situational awareness of malicious cyber activity across public and private sectors.
- The cyber information sharing and collaboration program (CISCP) is DHS's "flagship" program for public-private information sharing. Network partners share information about threats, incidents, and vulnerabilities.
- Enhanced cybersecurity services (ECS) is an intrusion detection and prevention capability that is available to public and private sector partners. It is a free service that protects networks against unauthorized access, exploitation, and data exfiltration.

- Automated Indicator sharing (AIS) allows the federal government and the private sector to exchange cyberthreat information at "machine speed" (US Department of Homeland Security 2016b).

Conclusion

Providing protection against all potential natural, accidental, and intentional threats and dangers cannot be accomplished by any single private or governmental entity. Combining the resources of both sectors has proved to be a mutually beneficial method to improve capabilities. Public-private partnership (PPP) information-sharing networks are communication networks that enable the flow of security and threat information between public sector law enforcement agencies and private sector businesses.

Public-private partnership · Disaster management · Disaster recovery · Disaster response · Private sector coordination

Definition

A public-private partnership (P3) is an organizational arrangement that can vary widely across contexts, particularly in disaster. According to The National Council for Public-Private Partnerships (NCPPP), as well as the US Government Accountability Office (GAO), a public-private partnership can be defined as "a contractual arrangement . . . between public and private sector partners" (GAO 1999). This is a typical definition, but in disaster contexts, public-private partnerships are not always contractual. P3s can be thought of as cross-sectoral coalitions that serve particular disaster-related needs that are not met effectively by any single sector. Involved partners can include entities from the public, private, or the nonprofit sector. North America, Asia, the Pacific, and Africa have witnessed a resurgent interest in P3s of all varieties in the last decade. Interest in this type of organization has been mixed across Europe and South America.

Introduction

Partnerships can be seen as spaces for merging motivations and values from entities in different sectors. In the public sector (and nonprofit sector to some degree), motivations for partnerships include realizing social goals, minimizing risk, democratizing a decision-making process, legislating, regulating, and navigating different authorities and political interests. Local public agencies can also be motivated by the perception of current or future lack of funding or support from higher levels of government. Private sector interests and motivations include achieving returns on investment, finding alternatives to other risky arrangements, changing market considerations, and realizing larger corporate goals (Reijniers 1994). Partnership allows interests to be coupled in pursuit of a shared goal.

Disaster public-private partnerships operate in all phases of the disaster cycle: hazard mitigation, disaster preparedness, response, and recovery. Mitigation operations are when organizations work to proactively decrease hazard exposure and vulnerability prior to a disaster event. Preparedness is the phase in which actors mobilize their "capacities and knowledge [to] anticipate and respond effectively to the impact of likely, imminent or current hazard events or conditions" (UN 2008). Preparedness activities can range from hours to years prior to a disaster event. Disaster response is the phase during and immediately following an event, in which immediate damage is assessed, prioritized, and reactive

projects are implemented (Zibulewsky 2001). Disaster response is, by nature, short-term, taking place hours, days, and sometimes weeks following an event. Disaster recovery-oriented partnerships operate in months or years following an event. These partnerships task themselves with the "process of restoring, rebuilding, and reshaping the physical, social, economic, and natural environment" (Smith et al. 2017). Partnerships may focus on a particular phase of disaster, which directs the types of projects they choose to prioritize.

Entities of all types and across all sectors can engage in public-private partnerships. These include but are not limited to governments, financial institutions, insurance firms, large and small businesses, educational institutions, faith-based organizations, professional associations, media, special districts and regional planning organizations, foundations, nonprofits, emergent groups, and individuals (Smith 2012). Some entities are bound by fewer laws, norms, and standard operating procedures than others. These more flexible organizations, such as professional associations, planning groups, and nonprofits, may naturally generate more opportunities for facilitating public-private communication and collaboration across all levels and sectors of organization (Smith 2012). Such groups may have the capacity to liaise between local residents and higher-level public and private entities. If mutually agreed upon, communication and collaboration can eventually take the form of a public-private partnership.

Leadership and Coordination

P3s often kick off through the efforts of a well-connected champion, usually an individual in a leadership position wishing to use resources towards an activity outside of what their organization typically engages in. P3 champions can be motivated to mobilize support for a partnership after perceiving a lack of funding or coordination support from federal or state governments (Chandra and Acosta 2009). Champions provide formal and informal leadership, as well as motivated partners to assume leadership roles at different levels of the organization (Simo and Bies 2007). Conversely, relying heavily on a partnership champion can leave the organization vulnerable to dissolving if the leading individual changes roles or organizations. Some partnerships attempt to address this challenge by a codifying partnership ambassador role, hiring designated partnership staff, and appointing supporting leadership roles (SDRP 2018).

After initial kickoff, P3s usually have at least two phases of planning their operations: milestone and activity planning (Reijniers 1994). Setting milestones involves visioning and mission-setting. Activity planning involves developing programs and projects to meet goals connected to the mission statement. Clearly defined geographic, organizational, and temporal scales enable the partnership to better orient its activities to unmet needs in communities or agencies that are managing the process of disaster mitigation, preparedness, response, or recovery. In some cases, while large, national-level organizations have aided short-term community recovery, long-term needs were met by smaller, locally led organizations who anticipate a drop-off of recovery support by groups and partnerships that lack long-term investment in the target community (Simo and Bies 2007). In these cases, conflict and effort duplication were managed or avoided through clearly articulated goals and well-defined scales of operation (Simo and Bies 2007). Partnerships keep on track by maintaining systems of project monitoring and progress reporting for partners, funding organizations, and/or communities they serve (Reijniers 1994).

Partnership Typology

Public-private partnership coordination can take a variety of forms, depending on the scale of organization, entities engaged, finance structures, shared goals, and phase of disaster. P3s can be arranged in reconstruction partnerships, partnerships for learning and information sharing, partnerships for planning and policy, as well as

partnerships for resource distribution (Chen et al. 2013; SDRP 2018).

Reconstruction partnerships are typically engineering and construction firms develop relationships with government agencies to inform infrastructure needs before, during, and following disaster events. Often, these arrangements span the spectrum of formality, with many starting as informal or pro bono before being codified through task force meetings and eventual organization formation. Others start contractually and carry on through later phases of disaster (SDRP 2018).

Partnerships for learning and information sharing tend to be less contractual than reconstruction partnerships. These organizations primarily aim to assist communication between government actors and private entities (including businesses, nonprofits, residents, universities, and civic organizations). Information-sharing partnerships sometimes have very specific intentions regarding the direction of information flow. Some primarily operate from the "ground up," or sharing information from a variety of actors at the local level directed to actors at central local, regional, national, and international levels of organization. Other partnerships may be more focused on information dissemination, providing a channel to communicate official information from government or corporate sources to members of a community or region. Many information-sharing P3s manage information traveling in both directions, with specific goals or projects attached to each process.

Finally, some partnerships focus on developing or informing public plans and policies for disaster recovery and resilience (SDRP 2018). These partnerships can create roadmaps for collective business continuity and mutual aid planning, municipal and regional recovery planning processes, or connect private sector perspectives with long-term questions and concerns of local, state, and federal policymakers (SDRP 2018). Planning and policy partnerships can be distinguished from learning and information sharing by their chosen time scale. Often selected timescales range from years to decades following a major event. Sometimes such partnerships are proactive and develop pre-disaster recovery plans for activation following a disaster event. Others form following an event to draft disaster recovery plans for similar time scales or engage in short-term policy changes such as building code modifications (elevation, proximity to hazards), construction standards, and re-zoning (Rotimi et al. 2011). Learning and information-sharing tend to prioritize present conditions, where planning and policy partnerships operate future-oriented.

Partnerships may be created for the explicit purpose of distributing material resources to residents prior to an event or survivors following the disaster. These P3s tend to be event-specific, with collaborations between major retailers with supply chain network infrastructure and expertise deemed suitable for disaster-related supply distribution (Stewart et al. 2009; Kapucu et al. 2010). Such partnerships are usually small and involve senior business leaders and government officials, with a goal of delivering a specified good or set of goods to target communities.

Disaster P3s can begin as loosely coordinated, untrained coalitions of concerned professionals who see common interest and mutual benefit in collaboration following a disaster event. While some types of partnerships are more active in certain phases of disaster than others, all types may have operations throughout the entire disaster cycle. Often partnerships organize and register as a 501(c)(3) or other nongovernmental organization in order to secure access to the widest range of funding sources to sustain partnership projects.

There are several ways in which becoming a 501(c)(3) helps disaster-related partnerships. In the United States, partnerships operating as 501(c)(3)s are excluded from taxes, and this status is required in order to apply for grants offered by local, state, and federal government as well as private foundations and other funding agencies. These grants may require that applicants commit other resources toward a project to generate greater buy-in by the applicant. Partnerships often are well suited for the collaboration required

to find matching funds or in-kind support for projects that support common goals. In addition, the financial and administrative capacities required of a 501(c)(3)s help partnerships maintain operations beyond the initial triggering disaster event (SDRP 2018). The work to draft a mission statement, often associated with official nongovernmental organization status, guides projects and interventions the organization chooses to engage in. Mission statements become an asset for preserving institutional memory about partnership intent, reducing the potential for coordination conflict down the line (SDRP 2018).

Training

Training is a major activity of P3s. Some partnerships run drills or facilitate workshops that train their own members, private sector leaders, or government actors in how to effectively work with each other. These efforts often involve expert facilitators guiding a discrete numbers of predetermined participants and audiences. Other partnership training efforts involve entire target communities, including residents and business leaders. These training processes usually intended to inform community trainees on programs, resources, and ways to safely act and operate during different phases of disaster. These training efforts may involve a wide range of actors, needs, and levels of expertise. Many of these larger partnership training efforts rely on the support of volunteer labor, which can be challenging to find in abundance during "blue skies" (or non-disaster operation), but difficult to manage alongside emergent needs following a disaster event (Quero 2012). If the partnership has an operating budget, they may hire part- or full-time coordinating staff to facilitate outreach and training programming (SDRP 2018).

Many partnerships engage all partners in regular outreach and programming in order to keep relevant entities organizationally on the same page with clear, rehearsed, understood channels of communication. Community- and resident-facing partnerships may also develop separate strategies for regularly engaging the populations they serve.

Engagement with partners or the public can take the form of a monthly meeting, volunteer days, disaster drills, workshops, shadowing, and workplace visits (SDRP 2018). Regular points of engagement sustain interest and motivation required for different types of organizations to effectively coordinate in later, more constrained contexts. Engagement has the added benefit of ensuring institutional knowledge and working organizational relationships are maintained, offering familiarity that serves the partnership's needs during a disaster event when all organizations lack time and capacity to form many new relationships and working dynamics.

Conclusion

Public-private partnerships have emerged as a way to incorporate the skills, resources, and knowledge of wider segments of the community and economy in overall disaster preparedness, mitigation, response, and recovery. P3 organizations range from disaster- and region-specific initiatives of local players to standalone organizations with national and international missions. They are often convened and strengthened by very active champions with personal and professional connections that motivate skilled and resourced partners. As climate disaster events become increasingly challenging to predict, and as human settlements expand into geographies previously thought too hazardous, motivated organizations will likely be required to think through creative strategies for funding and implementing disaster-related projects and interventions.

Rail security: rules, procedures, and processes to *protect* the railway system and efforts to *mitigate, respond*, and *recover* from attacks targeting rail bound traffic.

Introduction

Modern society is characterized by its interconnectedness, i.e., important critical dependencies exist which are essential to the maintenance of daily life. Rail bound traffic is a fundamental part of the so-called critical infrastructure of a society. Rail bound traffic, which is both passenger traffic, freight traffic, subway systems and its surrounding infrastructure, is an integral part of the overall transportation system. Trains are not only essential for the country's urban infrastructure but also for connecting people across geographic areas. Railway systems are also designed for accessibility and efficiency. However, critical infrastructure systems, including railway systems, also appear vulnerable to different acts of terrorism. A major current concern is that railway systems will be affected by cyberattacks. The terrorist events in Madrid in 2004 (almost 200 people were killed and nearly 2000 injured) and in London in 2005 (56 people were killed and 700 injured) are two examples of large-scale attacks which demonstrated the enormous consequences of a terrorist attack against rail bound traffic, not only in terms of human suffering but also in terms of major disruptions in vital societal functions. Attacks have also repeatedly targeted Russian railway and subway systems, including events in 2007, 2009, 2010, 2013, and 2017. Another example is the Brussels bombings in 2016, in which a bomb exploded on a train at the Maalbeek metro station. There are also several documented examples of thwarted attacks, and rail bound traffic is often mentioned in the media as a potential target for acts of violence. For example, there have been several reports on thwarted attacks in the United States, and New York's subway system has been identified as a main target.

In light of these major attacks on rail bound traffic, it is rather surprising that previous research has devoted extensive attention to terrorism targeting *other* forms of public transportation, including aviation and buses. Despite its inherent vulnerabilities, less attention has been paid to rail bound traffic (Strandh 2015a).

A Vulnerable Rail Bound Traffic

A general development in present-day terrorism is an identifiable shift toward more indiscriminate killings. Recent attacks targeting the public transportation sector have involved trucks, cars, and mopeds as weapons. As the examples already mentioned show, the rail bound traffic appears extremely vulnerable to attacks, and scholars (Jenkins 2001) even argue that, in the eyes of terrorists, it seems that rail bound traffic is becoming a "perfect" target to attack when the goal is to cause mass-casualty events. The question is then, why is the rail bound traffic so difficult to protect and what makes it a "perfect target" for terrorists?

1. *The open character.* One of the most distinguishing features of a rail bound system is its openness. There are few security measures on railway systems due to the need for easy passenger access and the railway system's wide geographical coverage. Passenger profiling, metal detectors, and patrolling police, all of which have become part of the landscape at airports, cannot be applied to rail bound traffic in the same way
2. *The possibility of anonymity.* It is, for instance, possible for the perpetrator to leave a backpack containing explosives on a train and then exit the train at the next station with several escape routes
3. *Large number of casualties.* Trains and railway stations mean large numbers of passengers in confined spaces, and this is attractive to terrorists who want their attacks to produce a large number of casualties
4. *Critical dependencies.* Attacks on railway systems cause enormous human suffering, but they can also cause major disruptions in vital societal functions. The risk for long-lasting cascading effects due to the disruption or destruction of a critically important infrastructure such as rail bound traffic is significant, and it becomes crucial to protect this sector against long periods of breakdown.

If terrorists seek to cause significant human suffering and cause major societal infrastructure consequences, rail bound traffic will most likely remain a target for acts of terrorism. The combination of the different inherent vulnerabilities associated with this transportation sector strongly indicates that the threat of terrorism can never be entirely eliminated. Hence, many researchers seem to agree that current available security and mitigation efforts cannot *completely* prevent attacks from occurring (Jenkins 2001, 2012; Waugh 2004; Strandh 2015a).

Attacks on Rail Bound Traffic: What Are the Main Characteristics?

First of all, terrorist attacks targeting trains or subway systems are nothing new. History provides us with plenty of evidence that trains, stations, and railway tracks have been targets of sabotage and attacks for a long time. However, like other means of transportation, rail bound traffic has now become a theater of operation for terrorists whose goal is to cause mass-casualty events (Jenkins 2001).

The phenomenon of terrorism targeting rail bound traffic is a *global* concern. Attacks take place in different parts of the world, and have done so since 1970, when terrorist attacks began to be registered systematically in research databases (Strandh 2015a). Using the Global Terrorism Database (GTD at the University of Maryland), Strandberg (2013, see also Strandh 2015a) analyzes attacks against rail bound traffic during a 40-year period. The results show that an overwhelming majority of the attacks since 1970 (1122 attacks in total) can be categorized as small ones that resulted in few casualties and limited infrastructure damage. This finding supports previous research on terrorism, which, in contrast to the widespread perception of terrorism as something that is always lethal, demonstrates that most terrorist attacks do not produce a large number of casualties. These minor attacks on rail bound traffic, with few casualties, are carried out by many different kinds of terrorist groups, and they are geographically diverse and tend to target different parts of the railway infrastructure. The analysis (Strandberg 2013; Strandh 2015a) also shows

another pattern, a rather recent development in which we can identify an increase in major, high-profile cases: nearly half of the 20 largest-scale attacks on railway traffic occurred after 2001. These attacks use a modus operandi designed to create as much destruction and fear as possible, including coordinated bombings resulting in multiple incident sites and attacks during rush hours. These high-profile cases result in complicated mass-casualty situations with an increasingly high number of casualties. In particular, the number of injured in the attacks has increased over the years. As mentioned earlier, the Madrid bombings, the London bombings, and the Brussel bombings are a few examples of this development.

Returning to the inherent vulnerabilities associated with rail bound traffic, the analysis over attacks since the 1970s shows that terrorists tend to target *different* parts of the railway sector. Forty-six percent of the attacks were targeting parked or passing trains. Yet, 22% of all attacks have targeted stations, and 17% have focused on railway tracks. Nine percent of the attacks were directed against railway support equipment, while freight trains were the target in 6% of the attacks. This confirms the picture of the railway sector as extremely difficult to protect and poses security dilemmas. For example, increased security measures at train or metro stations are considered an important security measure, but as the overview of attacks shows, 17% percent of all attacks target the actual railway tracks, and those attacks cannot be prevented by security measures at the stations (Strandberg 2013).

In terms of modus operandi, previous research (Frykberg 2002) contends that bombing is the most common method of attack. This is true also for attacks targeting trains. Bombs have been used in 78% of all railway bound cases. Armed assault accounted for 13%, and incendiary attacks were reported in 5% of all cases (Strandberg 2013).

The world has unfortunately experienced a number of high-profile terrorist events, and cases like September 11 tend to signal that terrorist strikes rely on highly sophisticated weapons, but the majority of attacks actually involve explosives or firearms. This is, as stated, also an accurate description of attacks on rail bound traffic. Bombs are relatively easy and inexpensive to construct, and it is widely known that terrorists use the Internet as a way to share detailed instructions about how to make bombs. A recent development is also that terrorist groups call for lone wolf perpetrators to use simple, improvised weaponry.

Another central question when trying to understand the characteristics of terrorism against rail bound traffic is the following: Who is behind the different attacks? Again, looking at the 40-year period, it can be concluded that there is a broad spectrum of terrorist groups behind the events. The Global Terrorism Database lists 150 different terrorist organizations that are responsible for attacks against this particular transportation sector. From a security perspective, it becomes interesting to note that what stands out is the high percentage of unknown perpetrators. In 51% of all attacks, there is no known perpetrator, and this once again confirms the picture of the rail bound traffic as problematic to protect and that the perpetrators can remain anonymous (Strandberg 2013).

The most recent data from the Global Terrorism Database reveals that there have been 25 large-scale attacks targeting rail bound traffic during the last 5 years (2013–2017). These attacks are events with more than ten causalities. There is a wide geographic distribution of the most recent large-scale attacks, including countries such as Russia, India, Thailand, Bangladesh, China, Egypt, and Great Britain. Pakistan stands out as the single most exposed country; 11 of the 25 large-scale attacks took place in Pakistan. Europe, which was hard hit by the London bombings in 2005 and the Madrid bombings in 2004, has not suffered any more attacks on the same scale. The attacks that have taken place since 2013 follow the same pattern as previous attacks in that regard that the different parts of the railway system are targeted. Bombings directed at passenger trains are the most frequent modus operandi, but there are also examples of armed assaults targeting train stations or sabotage of railway tracks. The phenomenon of suicide attacks is often discussed when analyzing present forms of

terrorism. One can note that 3 of the 25 most recent large-scale attacks were suicide events.

Hence, the pattern continues; a large majority of the attacks targeting rail bound traffic consists of smaller events with limited consequences, and they do not make headline news. Yet, the large-scale attacks do occur but not as frequent as the smaller ones. This causes a policy dilemma; should resources be allocated for investing in preparedness for such "low probability-high consequences events"? It is seldom that major large-scale cases occur, but if they do, their consequences will be enormous.

Rail Security and Emergency Management

As mentioned, high-profile terrorist events against trains are a rather recent development. If this trend continues, one can anticipate the need for highly complicated emergency management response efforts. Particular emphasis should be given to evacuation, search and rescue efforts, and medical care, because there are opportunities to save lives even after a terrorist attack. There is no universal solution to how to organize emergency management in the context of terrorism targeting rail bound traffic; however, there are some recurring critical points in the emergency management processes following the attacks.

A comparative analysis (Strandh 2015b) of attacks targeting Tokyo's subway system in 1995 and the bombings on commuter rail systems in Madrid in 2004, London in 2005, and Mumbai in 2006 illustrates some recurring challenges in the response. All cases showed how the response to a mass-casualty event is highly demanding in terms of (1) performing triage, (2) carrying out lifesaving measures, and (3) coordinating initial resources under circumstances of significant uncertainty and time pressure.

Important, however, is the realization that a terrorism-induced crisis also implies *additional* challenges. The large-scale events in Tokyo, Madrid, London, and Mumbai are examples of how these additional prehospital challenges can play out. (1) If a multi-site terrorist attack takes place (for instance, simultaneously bombings targeting a passenger train and a subway station), it will create several incident sites, which tends to make it extremely difficult for first responders to develop an understanding of the situation. As a consequence, it becomes difficult to grasp the extent and nature of the attack and to distribute resources and establish command structures at several parallel sites. (2) In a terrorism-induced event, scene safety emerges as particularly precarious. Secondary devices and exposure to dangerous substances are examples of the risks facing both emergency rescue personnel and victims. This also affects how assembly points and hospital tents can (or cannot) be established. (3) Security concerns call for rapid scene clearance, which, in turn, poses additional challenges because it leads to significant and rapid surge at hospitals. Evacuation and rapid scene clearance can be particularly challenging when trains are involved. The incident site, might, for instance, be located underground in a subway system or inside a railway tunnel. (4) The modus operandi of different terrorist groups results in specific injury patterns. The four cases mentioned here, Tokyo, Madrid, London, and Mumbai, were attacks involving chemical substances or bomb explosions. According to previous research (Frykberg 2002; Gómez et al. 2007), such injury patterns cause additional concerns. Persons injured in bomb explosions or shootings tend to bleed to death; thus, rapid action is needed. It is reasonable to assume that such injury patterns are far removed from what most medical services encounter on a daily basis. Instead, they are more often associated with injury patterns commonly found in war zones.

Rail Bound Traffic Actors: Fragmentation and New Roles

How to improve rail security and secure rail bound traffic from acts of terrorism has become a growing concern, and as pointed out several times, this particular transportation sector is extremely challenging to secure from antagonistic acts. This is due to its inherent vulnerabilities such as it openness. However, another aspect of this discussion relates to institutional aspects. Hence,

what characterizes this transportation sector in many countries is its *fragmentation.* This observation indicates that a paradox seems to exist. Thus, as stated, our society is becoming increasingly interconnected, and there are important dependencies in critical infrastructures, rail bound traffic included. While this seems to lead to the conclusion that critical infrastructures require a unified management, what we actually observe is increased organizational fragmentation (Strandh 2017).

Rail bound traffic is largely privately owned and consists of a multitude of different actors. The railway environment in many countries can be described as a patchwork of actors. Some actors are responsible for passenger traffic and others for freight rail. Some companies are domestic, while other operators are partly owned or wholly owned by international actors. There might be additional actors responsible for infrastructure, maintenance, and real estate. In addition, different government authorities are usually responsible for different questions relating to transportation and railway. Without a doubt, the often high number of participating actors and increased fragmentation raises questions about the possible implications of this development for security and emergency management. One could argue that more actors provide an opportunity to enhance security on the railroad in that sense that more actors are working dedicated to improve safety and security. However, one could also argue that an increased fragmentation runs the risk of creating vulnerability from a security and emergency management perspective. The organizational fragmentation is manifest, for instance, in unclear responsibilities, lack of overview over a multitude of actors, and an absence of a unified approach about how to mitigate and prepare for different forms of security challenges (Strandh 2017).

It can be noted that security work and terrorist attacks are foremost associated with intelligence, law enforcement, fire service, and emergency medical services. However, rail bound traffic actors increasingly, through private-public partnerships, assumed to take an active role when societal crises occur. An identified challenge is the railway sector's unfamiliarity with working in uncertain crisis settings, even though they are assumed to operate in the more peripheral parts of a response following a terrorist attack. Their role adheres foremost to avoiding a transportation breakdown and alternatively to resuming operation as soon as possible or communication to affected and stranded passengers. However, they nevertheless need to know their mandate and resources and have an understanding of the procedures that goes beyond daily operation. The question of whether an increased fragmentation of the sector improves or hinders their capacity to participate in such a process will continue to be discussed.

Efforts to Increase Security

There is no universal solution to the question of how to best enhance rail security and protect it from antagonistic acts. The response of security agencies and emergency management authorities have also varied around the world. A traditional approach is to focus on technical aspects of security or physical structures in prevention and preparedness. It is, for instance, widely known that London, which suffered from the bombings in 2005, use a vast network of CCTV cameras for surveillance. Such efforts are combined with extensive police patrols and intelligence work in order to thwart attacks. Even though security measures such as passenger profiling and metal detectors are not applied to the same extent as at airports, there are examples of increased security procedures at railway stations. For example, both Delhi and Moscow have comprehensive security procedures, searching for explosives and other weapons. However, a common discussion revolves around how to detect potential terror threats without compromising commuters' privacy.

Given the fact that rail traffic is so hard to protect, some researchers argue that protective security measures should focus on reducing the probability of an attack and *limiting* the damage caused by the attacks rather than focusing on eliminating *all* threats of attacks. Accordingly, so-called protective design is frequently discussed. Increased collaboration with architects

and designers in order to improve station design is one example. Another example is to develop a design of railway station which enables and improves evacuation flows in case of emergency situations. Also efforts to mitigate the effects of fires and explosions on trains and at stations are frequently being discussed (Strandh 2017; Holgersson 2016).

Another development shows that it is increasingly common for railway companies and security agencies to trust ordinary railway employees with the task to look for and report suspicious objects and individuals. In some countries, it is also common that ordinary passengers or visitors at a central station are encouraged to report suspicious behavior and activity.

Conclusion

In conclusion, railway systems can be a unique security challenge. One of the most distinguishing features of the rail bound system is its openness and thus its vulnerability. Trains, subways, stations, and tracks become attractive targets for terrorists for a number of reasons: the open character of the system, the possibility of anonymity, the large number of potential casualties, and the potential to disrupt critical infrastructure. A major attack on rail bound traffic can cause a highly complex mass-casualty situation which is demanding in terms of performing triage, carrying out lifesaving measures, and coordinating initial resources. Furthermore, it can be concluded that a terrorism-induced crisis also implies additional response challenges including several incident sites, scene safety for victims and rescue personnel, rapid scene clearance, and unique injury patterns. Moreover, rail security efforts are also closely related to the institutional rail environment, an environment which in many countries can be described as a patchwork of actors. An increased institutional fragmentation can create new vulnerabilities, for instance, unclear responsibilities, lack of overview over a multitude of actors, and an absence of a unified approach about how to mitigate and prepare for different forms of security challenges. Much remains to be done about rail security; however, the question of how to secure this transportation sector from acts of terrorism and other acts of violence keeps being discussed, and we can expect new rail security efforts in the future. Importantly, however, such security proposals must be realistic and suited for the unique character of the railway system.

Definition

A gated community is a residential complex with its boundaries enclosed by walls, fences, and embankments and has restricted access and other security systems to allow for the protection, safety, and comfort of the residents.

Introduction

The chapter examines residential security within the context of gated communities. Residential security involves the protection of people and their properties from the risk of burglary, home invasion, threats, disturbances, and other vulnerabilities. Thus, residential security is the type of protection that is offered to gated communities as it provides estate protection and other security solutions for the household.

The gated community has become an international trend over the last few decades. It consists of homes, green spaces, security guardhouses, electronic gates, controlled entrance, surveillance systems and enclosed by walls, fences, and embankments. This physical and symbolic separation of houses from the outside neighborhood is not a new phenomenon and many early examples, such as the Lincoln's Inn Field in 1735 and the Golden Square in 1750, date back to Western Europe of the eighteenth century (Porcu 2013).

At the entrance to the community, there is usually a guard booth operated by private security personnel and/or an automatic gate with remote control card access that is operated by residents. Visitor access to these premises is directed by the security guard in consultation with the resident, who is being visited, or by the resident him/herself who gives access through the remote gate. These properties are also equipped with pedestrian gates to allow convenience to authorized personnel to walk in and out of the premises. Speed bumps are also installed in these premises to regulate the speed of vehicular traffic thus making it safer for children to play within the grounds and for residents to more freely utilize the roadways.

These walled communities can be found in both rural and urban areas and are spatially organized to provide a picturesque view of houses, small streets, and green spaces. Many of these communities are equipped with parks, fitness centers, shopping complexes, meeting rooms, recreational facilities, and other common areas. Most of these properties are privately owned, making it legal to deny public access to the properties. However, some of these occupants are renters. The privatization of public spaces such as shopping malls and recreational parks within gated communities are facilitated by governments thereby limiting the use of these spaces to the wider public and giving the residents control over the complex.

In these communities, there are individual owners of the units while other parts of the property, such as clubhouses, swimming pools, and shared areas are owned in common by the residents. These communities are managed by associations which are comprised of residents who are elected as officers by the wider body of residents for the primary purpose of managing the affairs of the residential complex. The residents are required to conform with the bylaws of the association which stipulate the code of conduct and responsibilities of these householders. These bylaws would usually address issues such as usage of grounds, common areas, and facilities. A monthly association fee agreed by the owners is charged to the households by the association for securing the property and operating and maintaining common areas. These fees are often seen as double taxation by residents as they cover services such as trash collection which is already covered in taxes paid to local authorities (Lang and Danielsen 1997). The association sometimes takes some property owners to court to recover monthly fees owed. The law in some countries allows the association to legally force delinquent owners to sell their properties to recover substantial sums of monthly fees owed.

Motivation for Living in Gated Communities

Gated communities can be divided into three types. These are *security communities* where the focus is on the protection from crime, *prestige communities* where the orientation is on social status, and *lifestyle communities* where the core motivation is the availability of amenities for the convenience of the residents (Blakely and Snyder 1997). People move into these communities because of the fear of crime, fear of others, general safety, protecting property values, preservation of orderliness, and search for community, retiree needs, and regeneration of one's childhood neighborhood. Residents generally deem gated communities to be safer than the alternatives, regardless of what their primary motivation is for living in a gated community (Sullivan 2006).

Safety and Crime in Gated Versus Non-gated Communities

Living in a gated community allows for a trade-off between freedom and safety, i.e., freedom is curtailed due to the restrictions of the community while safety is promised with the use of manpower, barriers, and technology. People buy into gated communities to protect their families and properties from the risk of crime along with the urban unrest and instability that characterize modern society. Most of the affluent gated communities are monitored by 24-h private security guards while the not so affluent may use technological devices instead of guards. Some of the less affluent communities may not even use the technology but simply rely on the physical barriers as a mere psychological symbol of protection. These security measures and barriers afforded by gated communities appear to influence the residents' perceptions and sense of safety.

Safety is also thought to be facilitated by the restriction of visitor and vehicular access to the property. Some gated communities provide residents with a bar code for their vehicles. This allows for easy and quick access to the premises. The gates open and close in a few seconds after the bar codes which are placed on the car windscreen are scanned. This restricted access will allow for less intrusion of the properties and less opportunities for criminals to commit crimes. Thus, gated communities are designed to address the pervasive need for safety. Despite this view, there is no concrete evidence to support the belief that homes in gated communities are safer than those in non-gated properties (Low 2001, 2007).

For example, a study on gated versus non-gated communities in Newport Beach, California, Unites States, found no significant difference in perceived safety and actual crime rates between gated and non-gated communities – whether these communities were situated in high- or low-income neighborhoods (Wilson-Doenges 2000). Another study found that crime levels decreased after the development of gated communities but returned to previous levels in subsequent years (Fowler and Mangione 1986). Research is also suggesting that gated communities increase the feel of safety for residents while simultaneously increase the fear of

these residents for the outside world (Sarpong 2016). There is also the issue of domestic violence that take place behind the walls of gated communities as well as the con-artist usage of telephone scamming to steal from the elderly. Gated communities cannot prevent domestic violence since it is perpetuated by residents against family members or scamming since personal telephones are the channels used to commit this crime. However, more effective management and use of guards and surveillance of gated communities can prevent certain crimes, for example, burglary and other property crimes that sometimes occur in these residential facilities. Although a recent study found that surveillance systems within gated properties have led to the reduction in crimes, the overall research findings are mixed as to whether there is lower incidents of crime in gated than non-gated communities because the nature and organization of gated housing enclaves reveals that they can only mitigate certain type of crimes (Hedayati-Marzbali et al. 2017; Jacobs and Addington 2016; Reiboldt and Vogel 2001).

Affluence, Segregation, and Social Inequity

Gated communities are indexed to levels of segregation in the metropolitan areas of the United States. Therefore, an increase in the numbers of gated communities is expected to increase the levels of segregation in the country (Denton and Massey 1998). People also buy into gated communities in search for social and ethnic homogeneity amid the heterogeneity of urban societies. This separation also provides residents with a sense of tranquility as it creates a safe distance from the urban chaos and disorder (Caldeira 2000).

These gated complexes are described as common interest communities as they are designed to attract people of similar interests. These communities are also thought to address the desire for prestige and affiliation among residents (Low 2001, 2007). The communities provide exclusive usage of service and resources and are usually high-value properties that maintain value even when house prices within surrounding neighborhoods are falling. People opt to buy properties in these complexes because of the sustained property value as well as the perceived notion of safety in the living environment which also adds to the property value.

Residential gated facilities are seen as a place to live for people who share the same social status. They are also viewed as a place for children to grow up and play with peers of the same social standing and hence being isolated from some of the vagaries and deviant behaviors of the wider society. These enclaves are criticized for creating a place of segregation and social inequity within society (Low 2001, 2007). The properties are often thought to be a status symbol with the physical barriers perceived as a basis of economic inequality between neighbors living inside and outside the communities. As such, these properties engender an inward focused community culture driven by collective self-interest and bear the social cost of isolation and not identifying with the regions outside. And even on the inside, there are issues of *social trepidation* where residents are seemingly reluctant to speak with each other, even on trivial matters such as loud noises made by residents or children playing in unauthorized areas.

Neighborhood Watch

The neighborhood watch is a crime prevention strategy that is utilized by some gated communities. This involves the participation of residents in monitoring of the neighborhood to ensure that all suspicious activities and noncompliant behaviors, both within the community and in proximity to the community, are reported to the police. This vigilance by the citizens is of utmost importance as the police will always be constraint in providing the necessary 24-h monitoring of these surroundings. These neighborhood watch groups are indicative of residents' fear despite the leveraging of a range of security assets – paid manpower, barriers, and technology.

Security and Service Workers

Gated communities interact with the surrounding areas through service workers such as gardeners, nannies, and maids who are often drawn from

nearby low-income neighborhoods. These workers play a meaningful role in protecting community properties from the perspective of securing the property investment and providing *watchman-like* services for these properties. A case in point is the zone of gated communities near Belo Horizonte in Brazil where the gardeners employed to the communities were associated with the preservation of property investments through landscaping and manicuring of lawns thus keeping up the real estate values (Chase 2008). The well-kept properties also gave the impression that people are always around the place, even if not seen, hence providing another layer of security for the gated properties. These gardeners over time become social bridges between the gated and low-income communities because they build social capital between these communities thereby making the gated communities safer.

Conclusion

The gated community residents are the privileged few that are seemingly protected from the dangerous outsiders rather than the dangerous insiders. However, this preoccupation with the safety of the gated few diminishes collective responsibility for the safety of the masses thus perpetuating inequity within society. As such, living in gated communities is seen to increase the social capital among the rich and middle class who socially interact and share amenities and perceived safety behind these gates. However, the building of social capital in this exclusive manner does not bring social benefits to the wider society, as the outside majority is excluded from the added layer of protection that is offered by these properties. Thus, gated communities can be viewed as a temporary escape from reality as the space of fear outside these gates are always expanding. In effect, the security of people can only be improved, in a real way, when social exclusion and poverty are meaningfully addressed in the wider society.

Notwithstanding the perceived societal ills that have been associated with gated communities, the residents living within the complexes continue to benefit from the security, prestige, and lifestyle that are offered by these properties and are still holding on to the psychological feel of safety that is afforded by the barriers. Property values are also thought to be better maintained with gated communities even though the evidence varies based on location.

Definition

Residential security relates primarily to physical protection from external sources of crime-related harms potentially experienced by people in their abode and secondarily includes neighborhood safety as a partial prerequisite for being and feeling safe at home.

Introduction

Various forms of burglary constitute the most common threat to residential security (Weisel 2004). Burglary entails unauthorized access and removal of goods, sometimes simply by trespassing. In other cases, entry is forced – often referred to as "breaking and entering" – and damage to property can ensue even when offenders are unsuccessful in obtaining valuables. Burglars are generally motivated by material gain and focus on targets that are of immediate benefit to them, such as cash or goods that can be easily exchanged for cash (Bennett and Wright 1984; Weisel 2004). Unemployment and social marginalization are common, but not exclusive, factors in offender dispositions (Fallesen et al. 2018). Burglary rates are highly variable although burglary is widely viewed as a "volume crime," and surveys have shown victimization rates as high as 3% and 4% of households per annum in many developed countries (van Dijk et al. 2007, p. 66).

Dwelling places face a number of other security threats apart from burglary. "Home invasions" involve offenders entering a property seeking to obtain cash, drugs, or other goods by threats, sometimes resorting to torture or murder (Heinonen and Eck 2012). Other security breaches extend to graffiti and vandalism, voyeurism, sexual assault, kidnapping, assault, and murder. Multiple dwellings and high-density dwellings can be particularly prone to problems of disorder, excessive noise, drug dealing and consumption, and crime gangs. Residential security issues can also spill over into adjoining streets and parks, where crimes can affect the well-being and safety of residents in the wider neighborhood.

Vulnerability and Opportunity Theories

The best explanation for residential crime and specific vulnerabilities of different premises relates to opportunity factors – primarily low rates of guardianship and poor standards of physical security (Felson 1998; Weisburd et al. 2016). In that regard, the 1960s and 1970s saw a major shift in lifestyles that greatly enlarged opportunities for household crime, especially burglary. Traditional households often had 24-h natural guardianship, with several generations residing under the one roof and women at home engaged

in domestic duties and managing children. People generally stayed home at nights and weekends. The postwar economic boom allowed for greater freedom and mobility, with both parents in the workforce, children in day care and grandparents in retirement villages. This meant that residential areas emptied during the day; and enhanced entertainment and holiday options meant that many places were also unguarded at weekends and nights. Increasing prosperity generated an enormous proliferation of attractive targets in homes, including cash, jewelry, and electrical goods. These have been described as goods *craved* by offenders – that is, they are "concealable, removable, available, valuable, enjoyable and disposable" (Clarke 1999, p. vi).

Research has also shown that perceptions regarding access and egress affect burglars' selection of targets (Weisel 2004). For example, homes on grid pattern streets with multiple access and escape points often have higher rates of burglary compared to those on limited access roads. Cul-de-sacs are particularly well-suited to surveillance of potential offenders. The proliferation of motor vehicles in the postwar boom made a further contribution to ease of access to homes and escape with stolen goods. Motor vehicles on private premises were also an attractive target for thieves. Detached houses in sprawling suburbs provided multiple entry points and access through gardens and yards. However, larger housing complexes, whether private or public, can also be attractive because of limited surveillability and the anonymity provided by multiple occupancy (Armitage 2013). In addition, renting a home, or moving frequently, increases crime risks, with less in the way of personal and financial investments in security (Townsley et al. 2013). Residential burglary is also characterized by high rates of repeat victimization, with offenders gambling on further success against a known target within a few months of an initial burglary (Weisel 2004).

A number of other variables have been identified in residential crime vulnerabilities. In a groundbreaking study illustrating the principles of "Crime Prevention Through Environmental Design" (CPTED), Oscar Newman (1973) identified building design features affecting crime rates in two low-income high-rise "projects" in New York City. Both projects were "almost identical in overall size, density and population characteristics" (p. 38). However, in 1969 the Van Dyke project experienced 1189 crimes, including 52 cases of "malicious mischief" and 92 robberies, while Brownsville had a total of 790 crime incidents (34% less), 28 incidents of malicious mischief (46% less) and 24 robberies (74% less) (Newman 1973, p. 47). Further analysis indicated that the layout of the Van Dyke buildings facilitated crime, largely through offender anonymity, with concealed pathways, entries lacking visibility from the street, and with large load elevators and long corridors in the high towers. Brownsville buildings were lower rise (three to six stories), with observable "zones" and entryways visible from the street and smaller vestibules and elevators that helped residents get to know each other and made strangers or resident offenders stand out. Apart from a crime problem, Van Dyke also had more maintenance problems and a higher rate of tenant turnover.

CPTED principles overlap with the idea of "risky facilities" (Eck et al. 2007). Research in this area has highlighted enormous variation in crime rates between locations with similar functions. Within this concept, poor building design interacts with poor management strategies – such as tolerance of disorderly tenants or failure to provide adequate safety mechanisms. Negligent management practices can function as "crime enablers": high crime locations often have "fewer rules, lax enforcement, easy access, poor security, and other features that help offenders detect targets, commit crimes, and get away" (Eck et al. 2007, p. 240).

The post-1960s crime boom also highlighted the inadequacy of prevention through deterrence and incapacitation by the criminal justice system. In many locations, rates of arrest and conviction for volume crimes such as domestic burglary were as low as 5% (Weisel 2004). The inability of police to provide protection was highlighted in an innovative study by Felson (1998). The study estimated the amount of police on-site protection of premises in Los Angeles County were patrol officers are to be fully deployed. The data showed

that each location would receive 15 seconds of a police presence in 24 h. Doubling police numbers would provide 30 seconds of protection. "like putting two drops in a bucket instead of one" (1998, p. 9).

Home Security and the Crime Drop

A growing realization of the need to prevent crime by alternative or supplementary measures to the arrest and sanctioning strategies of the criminal justice system prompted rapid growth in the security industry internationally from the 1970s (van Dijk 2008). In-house and contract security services provided site-specific tailor-made interventions to close off opportunities for crime. The industry played "catch up" with rising crime rates until the 1990s when its impact became evident in the "international crime drop" (van Dijk et al. 2012). The decline in crime has been associated with diverse factors, including economic cycles, smarter policing, and increased imprisonment. However, analyses by van Dijk (2012) and Farrell (2013) indicated that enlarged "self-protection" strategies and "responsive securitization" provided the best explanation at the global level (van Dijk 2012, pp. 11 and 10).

Residential security provides one of the best examples of "securitization," where the installation of security devices, such as intruder alarms, has coincided with large reductions in burglary rates (van Dijk 2012). A good illustration of this association can be found in a study included in the 2009/10 British Crime Survey report, which found that "Households with 'less than basic' home security measures were six times more likely to have been victims of burglary (5.8%) than households with 'basic' security (0.9%) and ten times more likely than households with 'enhanced' home security measures (0.6%)" (Flatley et al. 2010, pp. 2–3). "Basic security" consisted of "window locks and double locks or deadlocks to outside doors." "Enhanced security" included these and one additional device, such as a security grill, sensor light, or alarm. Longer range analyses of the British survey have shown how the effects of improved security have been concentrated in reduced rates of forced entry and entry into unoccupied dwellings (Tseloni et al. 2017a, b). Offender surveys also support the view that security devices deter and frustrate burglars (e.g., Brown 2015).

Case Studies

The residential security literature includes a variety of case studies of successful security-based interventions. The following summaries provide a sampler of some of the more prominent ones across a diverse range of initiatives. In addition to the correlation studies outlined above, they show significant promise for large-scale benefits from improved target hardening and associated forms of enhanced guardianship.

"The Kirkholt Project," conducted in the late 1980s in the town of Rochdale in England, was focused on addressing high rates of burglary on a housing estate through the multiple situationally-based strategies of "target hardening," "target removal," and increased surveillance (Forrester et al. 1990). The interventions were developed following a diagnostic exercise which highlighted the phenomenon of repeat victimization, often within 6 weeks of the initial offense. Firstly, when a burglary was reported, a crime prevention officer visited the premises within a few days and carried out a security risk assessment. Recommended security upgrades – mainly, it appears, in the form of strengthened doors and locks – were paid for by the housing department of the local council. Secondly, coin-operated fuel meters were removed, and an alternative payment system was adopted. The meters had been attractive targets for thieves. Thirdly, an upgraded form of neighborhood watch was introduced, called "Cocoon Watch." The immediate neighbors of burglary victims were asked to keep a close eye on the burgled property and report questionable activities. Participants were provided with free security upgrades as an incentive and to expand the range of protection. The idea for Cocoon Watch derived from a finding that 70% of entry points used by burglars were visible to neighbors.

It was not possible to separate out the effects of the different strategies in the Kirkholt Project. Nonetheless, the evaluation showed that rates of burglary fell by 75%, from 44 per month in 1986–1987, the year before the project began, to 11 per month in the third year after implementation in 1989–1990 (Forrester et al. 1990, p. 27). This represented "a fall from approximately 25% to 6% per annum of the 2,280 households on the estate" (Tilley 1993, p. 2). In terms of the focus on repeat victimization, a major finding was that multiple victimizations reduced to zero. There was also no evidence of spatial displacement to neighboring locations. A financial cost-benefit assessment found that the interventions generated a total saving of £1.2 million (Forrester et al. 1990, p. 44). (See Cirel et al. 1977 for a similar project in Seattle.)

Another famous anti-burglary project – "Operation Identification" – was carried out in the late 1980s in a small community in Wales (Laycock 1997). The project sought to reduce the potential rewards from theft by creating a link between offenders and stolen property. Residents were visited by police and special constables who offered the free use of property marking equipment. On a return visit, officers inventoried the marked property. Deterrence was enhanced through extensive publicity and decals on doors and windows, and household participation rates reached 72%. The evaluation showed that there had been 91 burglaries among participating households in the year before the intervention. This reduced by 61% to 35 burglaries in the following year, with no evidence of displacement. In nonparticipating households, the victimization rate remained stable at 37 incidents before and 39 after the intervention.

A famous study of the effects of lighting is particularly interesting because its scope extended beyond individual homes to diverse crime types in a neighborhood area where up to 70% of crime occurred at night. Painter and Farrington (1997) reported on the introduction by the local authority of improved street lighting in the public housing estate of Dudley in England in the early 1990s. Natural surveillance was enhanced through upgraded lighting that greatly improved visibility. Surveys of residents were conducted in the experimental site and a control site in the year before and the year after installation. In the experimental site, victimization was reduced by 23% from 42% of survey respondents to 32%, whereas victimization in the control site dropped by 3% from 39% to 38%. (See also Painter and Farrington 2001 on positive results from a similar project in Stoke-on-Trent.)

A number of successes have also been attributed to the application of "Secured by Design" standards. This involves government certification of buildings that comply with a variety of CPTED and security hardware standards, often introduced as a police-led initiative (Hicks and Sansfaçon 2002). Certification normally attracts lower home insurance premiums. The Dutch Secured Housing label was introduced in 1989 and applied to new housing estates. It has been claimed that "the risk of dwellings being burgled . . . dropped significantly by 95% in new estates and 80% in existing environments" (Jongejan and Woldendorp 2013 p. 31). A case study evaluation of a program introduced in Rotterdam area in 1991 reportedly found that "Compared to households that did not participate in the program . . . households in the Secured Label program had a 70% reduction in burglaries . . . while rates of burglary were increasing countrywide" (Hicks and Sansfaçon 2002, p. 15). More broadly, a 2010 study found that, since a 1999 regulation extended required door and window security standards to all newly built homes, the burglary rate in this category fell "from 1.1 to 0.8 annually, reduction of 26%," without evidence of displacement (Vollaard and van Ours 2011, p. 1). Positive results have also been observed with the Secured by Design (SBD) scheme in the United Kingdom. For example, a study in West Yorkshire found that non-SBD properties experienced 22.7 burglaries per 1000 properties in 1 year compared to a rate of 5.8 for SBD compliant locations (Armitage and Monchuk 2011, p. 332; see also Armitage 2013).

Recognition of the problem of "risky facilities" (above) and management neglect stimulated innovations in holistic "place management" for improved amenity and security (Eck et al. 2007). In some cases, in a strategy referred to as "Third Party Policing," more responsible security-

focused management has been generated by police and local government pressure on landlords (Mazerolle and Ransley 2006). In other cases, landlords have initiated reforms in response to recurring problems. A good example is a management-focused program to address high crime rates and resident alienation in the large Mitchellhill public housing estate – consisting of five 19-story tower blocks – in Glasgow in 1989. The program involved the introduction of an on-site manager and assistant, together with 12 concierges who provided 24-h security-oriented services to residents (Davidson and Farr 1994). Other innovations included security hardware such as solid doors with barrel locks (which could be rekeyed for new tenants), better lighting, CCTV, controlled entry to foyers, and removal of internal landing doors that provided hiding places, along with increased police patrols and a "multi-watch" system for residents to report issues to police. Efforts were also made to improve the attractiveness of the estate with renovations and provision of furnished flats and tenant representation on the tenant selection committee.

An initial evaluation of the Mitchellhill program found that the total number of police-recorded crimes fell by 62% from 141 over 15 months to 53 in an equivalent period following the introduction of the concierge scheme (Davidson and Farr 1994, p. 26). In the same time periods, burglaries reduced by 71%, and theft of vehicles and theft from vehicles reduced by 72%. Large reductions in maintenance costs, mainly associated with vandalism, were also recorded, along with increased demand for flats, increased occupancy, and increased rental income. Program costs after savings were put at approximately £2 per flat per week (p. 33). Crime rates remained stable over the same period in a nearby comparable area. A brief follow-up evaluation, using 1991 and 1992 data, showed a partial regression, with the overall crime rate back up to approximately 50% of the pre-intervention rate. However, the large reductions for burglary and vehicle-related crime held firm (p. 33).

In an important sub-category of residential security applications, case studies have emerged in recent years of interventions to reduce repeat domestic violence and provide a safe setting for victims of family violence to rebuild their lives (Prenzler and Fardell 2017). Programs usually work through free security hardware upgrades on victims' homes, including rental accommodation, to protect against a range of threats and intrusions that can follow from separation and adoption of a protection order – including harassment, abduction, assault, and murder. Although available studies have not included control groups, a review of six within-group evaluations showed consistent extremely positive outcomes for participants in terms of reduced offenses and improved feelings of safety, including for children (Prenzler and Fardell 2017). Monitored duress alarms, with a police priority protocol, appeared particularly valuable in supplementing target hardening. Safety in domestic violence shelters also represents an important sub-category of residential security, entailing the need to integrate high security standards with the needs of clients – often including children – for privacy, amenity, and easy access (Gierman and Liska 2013).

Conclusion: Best Practice Principles

The research on residential security has generated a number of valuable guides for optimizing prevention (e.g., Draper et al. 2017; Heinonen and Eck 2012; Sampson 2001; Weisel 2004; see also Security Management, Physical Security: Best practices, Physical Security: Audits). An important principle involves making the best use of available target hardening devices to optimize deterrence and denial of offenders – ensuring equipment is of quality design and materials with no gaps allowing easy access. More generally, design principles emphasize the value of "defence in depth," beginning with appropriate access control measures at the perimeter of a residential setting. Concentric rings of protection allow for the operation of the "5 Ds" of physical security: "deter, detect, deny, delay and defend" (Marier 2012, pp. 1–2). Each layer of protection should operate to impede or block an intruder's progress toward targets, as well as impeding their escape. High-grade detection systems and target

hardening are particularly important in the defense of high-value assets.

Most importantly, however, guides generally emphasize the necessity of a problem-solving process in diagnosing residential crime problems and risk factors, including resident input, matching interventions to risk, engaging in regular system tests to ensure currency, and balancing security with amenity and fire safety criteria. Making the most of security technology as it improves in quality and becomes more affordable and convenient is also fundamental to a "continuous improvement" process. For example, innovations in CCTV functionality now allow for internet-based remote verification of alarm activations on computers and mobile phones, substantially mitigating the long-term problem of false intruder alarm activations and ensuring a valid rapid response from police or security firms (Sampson 2011).

Residential security can also be enhanced through collective efforts. Small regular financial contributions by residents of apartment buildings allow for the engagement of security firms and/or the employment of a facilities manager or concierge with security duties (Townsley et al. 2013). This can also work in "gated communities" of detached or semidetached houses. In these contexts, the concept of crime prevention through effective "place management" has enormous potential (Eck et al. 2007).

Finally, it should be noted that many advocates of securitization for residential crime prevention also adopt both pragmatic and social justice imperatives in support of welfare programs to address poverty and neglect as causes of both victimization and offending (e.g., Forrester et al. 1990). Offender motives can be addressed through a variety of social support measures, including employment programs (Fallesen et al. 2018). Victim vulnerability can also be addressed through enhanced employment, as well as subsidized security and mandated security standards in public housing – possibly obviating the need for alienating crime prevention measures such as segregated high security communities. The case studies described above also demonstrated the value of crime prevention partnerships in bringing together groups such as police, local government, tenants, security companies, and charities (such as domestic violence support services) in addressing residential security challenges.

Keywords

Internal retail crime · Fraudulent disbursements · Intellectual theft · Embezzlement · Larceny · Skimming

Definition

Retail employee theft involves "the theft of anything of value from the retailer by an employee or accomplice" (Mishra and Prasad 2006, p. 817). Five specific crimes are categorized under employee theft or asset misappropriation – fraudulent disbursements, intellectual theft, embezzlement, larceny, and skimming (Bailey 2006).

Introduction

Employee theft includes misappropriation of tangible and nontangible assets through fraudulent disbursements (e.g., paid for time not worked), intellectual theft (e.g., selling information to competitor), embezzlement (e.g., stealing cash), larceny (e.g., stealing merchandise), and skimming cash from the register (Bailey 2006). Retail stores sell a variety of goods (e.g., clothes, food, drugs, music, candy) for public consumption and use but lose a significant portion of their profits due to employee theft (Martin et al. 2014). Retailers purport that embezzlement, larceny, and skimming by employees, either alone or in collusion with accomplices, likely accounted for one-third to two-fifths of their cash and merchandise losses (see Hayes, Weitz, & Hollinger's National Retail Security Survey, reported in Martin et al. 2014). This belief is consistent with research findings that internal theft was the second leading source of merchandise shrinkage. According to the 2018 National Retail Security Survey of 63 retailers (Moraca and Hollinger 2018), employee theft comprised 33.2% of the $46.8 billion in economic loss for the retail industry in the USA alone. This estimate of loss from employee theft reflected a slight increase from the year before but represented a decline from the rates of 35.8% in 2016 and 34.5% in 2015 (Moraca and Hollinger 2018).

Retailers are concerned about the number of employees involved, how often they steal, and the length of time they offend prior to being apprehended. A recent examination of federally processed cases revealed that one-third to three-fourths of employees commit employee theft at least once, and for 28.7% of the retail cases, theft occurred repeatedly over months or even years (Karpp 2017). The length of time employee theft continues may depend on whether other employees witness it and are willing to report it. According to Kessler International (2013, as cited in Martin et al. 2014), 45% (225 out of 500) of employees in retail and service companies were aware of or witnessed employee theft. Employees are in a good position to report crimes to their employers and will do so when the organizational climate is conducive with this behavior (Avery et al. 2012). For example, 53% of the tips that led to the initial detection of occupational fraud came from employees reporting other employees (The Association of Certified Fraud Examiners/ACFE 2018), whereas 54% of retail employee theft had been detected by the management (Fikes 2009).

To combat employee theft, the majority of retailers rely on the services and investigations of loss prevention personnel (see ▶ "Retail Security: Use of Security Guards" and ▶ "Security Guards: Authority and Power" chapters in this volume). According to a study by Moraca and Hollinger (2018), 63 retailers indicated that their 2018 loss prevention staffing and budgets, which averaged 0.74% of their sales, either remained constant (44.4% and 42.9%, respectively) or showed growth of 35.5% (for both). Retailers also increased their use of loss prevention systems, such as closed-circuit television/CCTV (27%), training announcements (15.9%) and videos (9.5%), and theft deterrent devices (7.9%), which also affected both shrinkage and offender apprehensions (Moraca and Hollinger 2018). The combination of LP management strategies, reliable electronic article surveillance (EAS) systems, and CCTV placement and use has been credited with reducing retail shrink from all sources (R. McCrie, January 11, 2019, personal communication).

Despite retailers' efforts in prevention, detection, and investigation of loss, employee theft is still a major concern. Employee theft contributed to a 5% loss of businesses' annual revenues, resulting in a global loss in the trillions and led to bankruptcies in various small businesses that included retail, manufacturing, trade, and service companies (Kennedy 2017). Moraca and Hollinger (2018) reported that the responses against dishonest employees, such as average number of apprehensions (506.1 vs. 834), terminations (397.8 vs. 651.6), prosecutions (104.4 vs. 209.6), and civil demands (125.1 vs. 344.5), declined in 2018 compared to 2015. In contrast, a larger investigation using a base of 1.4 million employees at 21 large retail companies with 16,409 stores (the

30th Annual Retail Theft Survey, Jack L. Hayes International 2018) found that 40,286 of the employees who committed theft were apprehended in 2017, roughly accounting for 1:35 employees and resulting in the recovery of nearly $38 million dollars. The conundrum for retailers, whose goal is to reduce loss, is determining whether they should focus more on internal rather than external theft or simultaneously attend to both. Based on the 2017 survey results, retailers were able to increase apprehensions and recover losses by eliminating dishonest employees quickly, launching investigations by specialized loss prevention personnel, and installing software geared to identify dishonest employees (Jack L. Hayes International 2018). This entry focuses on describing employee demographics, motives, and crime methods. It also provides legal responses for retail employee theft and suggestions to improve effectiveness in reducing employee theft.

Descriptive Characteristics of Employee Thieves

Researchers have linked specific characteristics – age, sex, ethnicity, tenure or seniority, and position – to employee theft, but keep in mind the relationship of these variables represents correlations rather than causal factors. It is also important to note that demographic features of employee age, sex, and ethnicity of retail employee thieves are contingent upon the distribution of those features in (a) the area residents who comprise the applicant pool for employment and (b) those apprehended employees (i.e., not all of them will be caught; thus, their characteristics will be missing or misrepresented). For example, ACFE (2018) reported that men comprised the highest proportion of occupational fraudsters in every country from 2008 to 2018, but the proportion varied by region (e.g., 58% in the USA, 69% in Canada, 77% in Western Europe, 92% in Middle East and North Africa).

With those caveats in mind, an overall description of employee thieves as young men, ages 18–22 years, with low-level employment positions held for a short term is based on data from two studies. Fikes (2009, p. 32) examined 502 dishonest retail employees (ages 16–55 years) who were apprehended, investigated, and terminated for theft (i.e., cash, merchandise, rewards abuse, services, point-of-sale abuse) from July 2007 to June 2008. She reported that the offenders in her sample were *white* (55%), *men* (59%), and *young* (48% were between ages 18 and 22 years old). In terms of their employment, they were mainly *low-level positions* (88% hourly employment hourly) with *short-term tenure* (36% up to 6 months).

Baxter (2014) used 678 case reports of dishonest employees (ages 18–47 years) apprehended from 2005 to 2012 from a retail chain with 1089 stores operating in the USA, Puerto Rico, and Canada, specializing in young adult apparel. The typical employee thief was *male* (53%) and *young* (M age = 23 years, $S.D.$ = 4.77, most often ranging from 19 to 22 years based on 678 cases). They commonly held low-to-middle-level positions as marginal/sales associates (61.5%) or as assistant managers (25.9%) but were most likely to have short-term employment tenure (ranging from 2 to 9 months for 156 cases).

In comparison to older employees who have been with their company for a long time, younger employees who have worked a short time period are more likely to commit employee theft (Kennedy 2017). There is some evidence to show that older employees exert positive, moral influence over their younger colleagues by discouraging theft, perhaps resulting from the development with age of crystalized intelligence that fosters their ethical and responsible beliefs and behavior (Avery et al. 2012).

These characteristics may impact employee theft differently when considered in light of other aspects, such as company size. Karpp's (2017) analysis of 104 federal court cases of retail employee theft revealed that most embezzlements were committed by low-level employees (65%), especially those in companies with less than 100 employees (76%). Employee sex also covaries with the size of the company. Karpp (2017) reported that 50.2% of small business thieves were women, but 54.7% of large business thieves were men. Company size also interacted with age and sex. The median age of

female employee thieves was 48 for small businesses, but 43 for large businesses, whereas the median age for male employee thieves was 49 regardless of business size.

Employee theft was affected by the number of employees involved (e.g., collusion) and one's employment position. An examination of 90 Canadian cases of occupation fraud (post 2004) by Peltier-Rivest and Lanoue (2011) revealed that employees were more likely to steal alone than with accomplices, but the average and median loss was higher for the latter than for the former. They also reported that the median loss was usually higher for men than for women, which they attributed to limited employment position within the organization resulting in fewer opportunities for women than for men to have access to and control over large cash amounts. Large economic losses through fraud and embezzlement were often associated with those in a position of authority and financial control (e.g., owners, managers, executives), who were successful at stealing without detection because they knew the loss prevention system so well (Kennedy 2017) and had greater access to company assets than lower level employees (Peltier-Rivest and Lanoue 2011). Education level has also been positively related to employee theft, but this is likely due to the relationship between academic requirements for higher level employment opportunities.

Typical Motives for Employee Theft

Employees have a variety of motives for behaving dishonestly, such as engaging in stealing (i.e.,property deviance) and/or being counterproductive (i.e., production deviance) at work that stem from both individual and organizational factors (Martin et al. 2014; Moorthy et al. 2015). The relationship between property and production deviance is 0.48, and employee dissatisfaction at work may prompt motivation for employee theft (Hollinger and Clark 1983, as cited in Baxter 2014). Retail employees engage in theft based on three individual components – *financial need*, *opportunity*, and *personal characteristics* (Baxter 2014; Martin et al. 2014; Moorthy et al. 2015). Employees' debts and expenses, particularly when they are financially desperate (e.g., due to gambling and/or substance addictions), play a major role in fraud (Baxter 2014; Moorthy et al. 2015). However, most employees will not resort to theft unless presented with opportunity, such as failure to supervise, check, audit, or inventory (Baxter 2014; Martin et al. 2014; Moorthy et al. 2015). Employees who exhibit negative personal characteristics, such as greed, entitlement, lying, deceitfulness, and impulsivity, may commit theft and fraud, especially when surrounded by other employees engaged in similarly deviant behaviors (Martin et al. 2014; Moorthy et al. 2015).

Employee theft is also effected by organizational factors of *compensation*, *justice*, and *ethical work climate* (Baxter 2014; Moorthy et al. 2015). The perception that the employee is not compensated fairly for the work he/she produced may motivate theft as a means of restoring equity (Chen and Sandino 2012). As employee wages were negatively correlated with employee theft, high pay and quality of employees (relative to their peers) were associated with low occurrence of employee theft (Chen and Sandino 2012). Employee theft may also be motivated by the perception that the organization does not treat staff fairly and justly (Moorthy et al. 2015). Employees will work hard, be productive, and be absent less when compensated fairly and treated justly but may seek revenge when they are not (Martin et al. 2014; Nemeth 2019). Another motive for employee theft stems from the organization's ethical work climate as honest or dishonest (Moorthy et al. 2015). Employee theft is likely to be facilitated and maintained when the perception is that the actions themselves are low risk. Moorthy et al. (2015) explain that employees determine whether to engage in theft based on whether coworker theft occurs and is punished; stealing is easy to do because of lack of internal controls (e.g., policies, practices, and procedures), such as formal monitoring (e.g., hidden surveillance); and intention to steal is present.

Methods for Employee Theft

Kessler International (2013 as reported in Martin et al. 2014) indicated that nearly 475 out of 500 respondents from retail and service companies admitted to *production deviance*, specifically stealing time (e.g., 30% falsified time worked, including taking unauthorized breaks, 63% checked social media sites during work day) and *property deviance*, including taking office supplies and services (e.g., pens, paper, notepads). To understand employee theft, loss prevention personnel should acquaint themselves with the five typical methods, which can be categorized as "intangibles," such as fraudulent disbursements and intellectual theft, and "tangibles," such as skimming, embezzlement, and larceny/theft (Bailey 2006).

According to Mishra and Prasad (2006), *fraudulent disbursements* refer to misappropriation of assets by employees and involve multiple on-book fraud schemes (see Table 1 for a description of these methods). Employee thieves falsify store records to conceal the loss of merchandise or cash. Although it is impossible to determine how much loss is due to fraudulent disbursements from the various schemes, it is likely that some if not all of it is encompassed in the combined administrative/paperwork error (18.8%), vendor fraud/error (5.8%), and unknown error (6.6%) as indicated by retailers in 2018 (Moraca and Hollinger 2018). *Intellectual property theft* refers to stealing a company's trade secrets, including ideas, products, and strategies for the sale of these products (see Table 1). Kennedy (2017) reported that 4.5% of the employee thefts in his study of small retail and nonretail businesses involved intellectual property.

Within retail stores, employee theft of tangibles from highest to lowest degree is checkout, sales floor, and customer service (Mishra and Prasad 2006). For example, Fikes (2009) indicated that 38% of employee theft was point of sale, 26% was merchandise theft, and 24% was rewards abuse. Performing refund fraud was the second most common method of employee fraud in retail stores found in Baxter's (Baxter 2014) study, accounting for 34.8% of the cases (pp. 164–167). Baxter also reported that the highest incident rates for retail employee theft were stores in suburban (55%) and mall locations (78.7%).

Kennedy (2017) specified that cash, ranging from $5 to $2 million, was the most stolen object by employees in small retail and nonretail businesses (43.2%). As indicated on Table 1, cash theft is predominantly obtained through two methods – skimming and embezzlement. *Skimming* occurs when cash is taken by the employee at the point of sale but before it is recorded. *Embezzlement* refers to theft by a retail employee who has legal access to the property, such as a cashier who takes cash from the register, whereas a store clerk who takes money from the register is committing property theft or larceny.

Retail employees also commit *larceny* when they steal or fail to pay for merchandise or discount merchandise for themselves or others without authorization (Mishra and Prasad 2006). Larceny is categorized under property crime offenses and is defined as the "unlawful taking, carrying, leading, or riding away of property from the possession or constructive possession of another" (Federal Bureau of Investigation 2016) with felonious intention (Nemeth 2018). The level of severity for larceny –misdemeanor or felony – depends on the dollar value of the items, but the criteria are determined by jurisdiction. Baxter (2014) found that employee theft was committed primarily by passing or removing merchandise from the store in 52.5% of the cases (pp. 164–167). Employee theft of merchandise through sweethearting contributes significantly to retail shrink. "Sweethearting," the practice of giving customers unauthorized free (e.g., samples) or discounted merchandise, contributes up to 35% of profit losses that totals billions, mainly because it is seen by employees as promoting customer satisfaction (Martin et al. 2014).

Many employee theft incidents are not one-time incidents (Karpp 2017). For example, Kennedy (2017) found that most of the 44 retail and nonretail employee thefts reported were ongoing schemes (59.1%) lasting on average 16 months (range of 2 weeks to 20 years). Similarly, a recent report by the ACFE (2018) showed

Retail Security: Employee Theft, Table 1 Criminal Offenses and Methods

Criminal offense	Methods
Fraudulent disbursements	Payments to the employee using his/her employment position to obtain payment for inappropriate purposes, including: (a) Check tampering schemes (e.g., forging signature of payee or endorser for oneself or accomplices; cashing fraudulent checks; reissuing outstanding checks; account and wire transfers paid to themselves) (b) Billing schemes (e.g., false vendor payments to themselves or accomplices, petty cash disbursements) (c) Payroll schemes (e.g., forged payroll checks, commission payments not earned, checks to terminated employees, overtime for time not worked, worker's compensation) (d) Expense reimbursement schemes (e.g., payment for expenses never incurred; duplicate payment) (e) Register reimbursement schemes (e.g., coupon stuffing, credit card reimbursement to self or accomplices, stealing customer credit card information) (f) Misusing benefits and policies (e.g., medical and healthcare frauds including undeserved sick leave or vacation days) (g) Tax-related frauds (e.g., charitable and religious contribution frauds) (h) Insurance fraud (e.g., false claims of amount and/or cost of merchandise and cash loss) (i) Forgery and document tampering (Mishra and Prasad 2006; Nemeth 2019)
Intellectual property theft	Taking intangible assets, such as corporate information, that give a competitor an advantage over the retailer, including: (a) Proprietary information/products (b) Client lists (c) Marketing plans (Martin et al. 2014)
Skimming	Cash is pocketed by cashier or manager prior to it entering the register (without record) to deprive the merchant from full retail price by personally or in consort with another: (a) Voiding sale (b) Hitting "no sale" (c) Overcharging (d) Shortchanging (e) Under ringing (f) Crediting for nonexistent returns (g) Getting refunds using discarded customer receipts (ACFE 2018; Mishra and Prasad 2006; Nemeth 2018, 2019)
Embezzlement	Cashiers and/or managers (who have authority to handle money) take cash from the register, safe, or bank deposit bag (Mishra and Prasad 2006)
Property crime: larceny retail theft offense [specialized statute]	Thief takes possession of, carries away, or transfers merchandise without paying full retail price by personally or in consort with another: (a) Altering, transferring, or removing price tag (b) Transferring merchandise from original container to another container or a concealed location (including bag, box, or garbage for later retrieval) (c) Making inoperable inventory control tag or security strip (d) Taking merchandise through unsupervised exits (e) Stealing from returned goods and layaway (f) Shipping stolen merchandise to their own address (g) Damaging merchandise purposefully to purchase at discount and/or substituting damaged merchandise for undamaged goods (Nemeth 2018, 2019)

that employees were able to avoid detection on average for register disbursements and on-hand cash about 12 months, for noncash theft and skimming about 18 months, and for cash larceny about 24 months.

Retailer Responses to Employee Theft Within the Law

A professional investigation is conducted to determine whether employee theft has occurred

(see ►"Investigations: Employee Theft of Employer Property" chapter in this volume). Once confirmed, then retailers may pursue criminal charges through prosecution and/or file for civil recovery to obtain restitution for losses (Fikes 2009) (see ►"Investigations: Criminal", ►"Investigations: Employee Theft of Employer Property", ►"Investigations: Criminal", and ►"Law: Administrative" chapters in this volume). To file criminal charges, two types of evidence are required. First, there must be documents, video, or written admission by the employee that the merchandise offered for sale, stored, or on display was taken (i.e., be in possession of it). Second, it must be shown that the employee intentionally deprived the owner of it by (willfully) carrying it away, concealing it, converting it (i.e., altering the price of the merchandise, removing the inventory control tag, or making the tag inoperable), or failing to pay for it (International Association of Professional Security Consultants/IAPSC 2015, p. 3; Nemeth 2018, p. 171).

Kennedy (2017) reported that only 16% of the 64% of small businesses (retail and nonretail) who experienced employee theft reported it to police. In their examination of occupational fraud, ACFE (2018) reported that the pursuit of criminal charges had declined over the past 10 years (69% in 2008 to 58% in 2018, p. 48). Yet, when criminal cases were presented to the prosecutor, most of them were accepted for trial (82%), mainly resulting in guilty/no contest pleas (53%) and convictions (20%), with only a 1% acquittal (ACFE 2018, p. 49).

Even when investigations yield the requisite evidence for prosecuting the employee, other factors should be considered. Specifically, the amount of time involved of the owner/manager and other employees in the prosecution process, including interviews by the police and court appearances, as well as economical considerations due to the cost of wages and travel payment for the witnesses, help determine this decision. Unfortunately, even when the trial yields a guilty verdict (or the defendant takes a plea), the judge may sentence the defendant to jail, prison, or even probation but may not include restitution. ACFE (2018) indicated that only 15% of companies recovered all of their losses; most companies recovered none (53%) or some (32%) of their losses from occupational fraud (p. 51).

Retailers who wish to consider pursuing criminal charges must also balance the evidence against the cost of the merchandise in determining what benefit legal charges will have. For example, Fikes (2009) reported that the majority of cases involved losses of up to $24 (39%) and between $25 and $199 (20%), which likely discouraged the retailer to prosecute. ACFE (2018) indicated that recovery was negatively related to the amount of the loss, such that 30% of companies recovered all of their losses if it was under $10,000, but only 8% were able to do so if the loss was over a million dollars (p. 51).

Employers decide against filing charges of occupational fraud against employees based on their desire to sever ties quickly through firing the employee, particularly due to the emotional strain of the betrayal, their beliefs that the police are ineffective, or because their attorneys advised against it (Kennedy 2017). ACFE (2018, p. 50) indicated that the top three reasons that companies chose not to involve law enforcement were impact of bad publicity (38%), belief that internal discipline resolved it (33%), and the cost (24%). Instead, companies chose simply to terminate employees for retail theft (87%, Fikes 2009) and fraud (65%, ACFE 2018), without filing charges. Termination as a punishment, however, was mediated by the offender's position in the company (ACFE 2018, p. 48), such that it was more likely at the employee and manager levels (e.g., 72% and 67%, respectively) than at the owner/executive levels (44%).

An alternative to criminal prosecution is civil lawsuit; this remedy will allow the retailer to be reimbursed for the cost of the stolen merchandise and sometimes even the cost of the investigation. The results from the ACFE (2018) survey indicated that about a quarter of the fraud cases against employees were processed through civil suits, with favorable judgments for the retailer (53%) or through settlement (27%). Voluntary restitution involves the employee returning merchandise that is still in saleable condition that they

or others still possess, including in pawnshops. Employees may also make restitution using their final paycheck and unused benefits (e.g., holiday pay). To determine which solution for employee theft is best for the retailer, guidelines should be created in conjunction with representatives from Human Resources, Loss Prevention, and Operations.

Conclusion

Organizations struggle with the issues of trust and balancing relations between supervisors and employees, decisions of punishment and restitution, and how best to implement security prevention and detection tools (Cunningham 2017). Employee theft and the methods employed to counter it contribute to 30% of businesses becoming bankrupt, nearly closing, or failing, as well as employee layoffs and loss in bonuses and raises (Mishra and Prasad 2006). Communities lose important revenue though commercial taxes on the items that were stolen instead of being purchased and on income taxes from stores when retailers move out of the neighborhood due to the high losses suffered from employee theft. Store closings, in turn, increase unemployment for those in the affected areas, as well as impact the economic well-being of the nation.

Applying a routine activities theory approach, employee theft occurs when a suitable target is available, the offender is motivated, and a capable guardian is absent (Martin et al. 2014). Fikes (2009) found that managements' failure to adhere to policy and procedures provided associates with the opportunities to steal for 77% of the cases. Each organization must examine their own cases of employee theft to determine which situational and behavioral factors played a role (Kennedy 2017). Retailers must then implement individual- and organizational-level changes to counter employee theft, such as increasing perception of punishment as certain and swift; prescreening employees; using technology (CCTV), random inventory checks, peer detection, and control; and creating a culture of intolerance for employee fraud and abuse (Avery et al. 2012; Kennedy 2017). By closing the gap (i.e., hardening the target, reducing motivation for the offender, and increasing the guardian's effectiveness), retail shrink through employee theft can be reduced.

Retail Security: Shoplifting

Lauren R. Shapiro
Department of Security, Fire, and Emergency Management, John Jay College of Criminal Justice, City University of New York, New York, NY, USA

Keywords
Inventory shrinkage · Shop theft · External retail crime · Loss prevention and asset protection · Adult and adolescent shoplifters

Definition

The Federal Bureau of Investigation (FBI 2016a) categorizes shoplifting in the Uniform Crime Reporting (UCR) as larceny-theft under property crime offenses, defined as "unlawful taking, carrying, leading, or riding away of property from the possession or constructive possession of another." Retail shoplifting refers to "the theft of goods by customers from retail premises during opening hours" (Wittenberg 2009, as cited in Hirtenlehner et al. 2014, p. 14).

Introduction

Retail stores sell a variety of goods (e.g., clothes, food, drugs, music, candy) for public consumption and use. Inventory shrinkage is a serious problem for retailers globally, with external theft/shoplifting in 2017 accounting for 37% of the $49 billion in economic loss for the retail industry in the USA alone (National Association for Shoplifting

Prevention [NASP] 2014a; Moraca and Hollinger 2017). Although alarming, this statistic actually represents a reduction from shoplifting incidents, one of the largest sources of shrink, which was 39% in 2016 and 38% in 2015 (NASP 2014a). NASP (2014a) reported that other sources of shrink stemmed from internal/employee theft (30%), administrative error (21%), vender fraud/error (5%), and unknown (7%).

Even more disconcerting, only 10 million shoplifters out of an estimated 27 million shoplifters in the United States over a 5-year span had been caught (NASP 2014a). Juveniles comprise one-fourth of shoplifters and adults comprise the rest (NASP 2014a). Larceny-theft encompassed 71% of all property crime offenses in 2016 (FBI 2016a). Shoplifting offenses affect every region of the USA, comprising 24% of larceny-theft offences in the Northeast, 23% in the Midwest, 22% in the South, and 22% in the West (FBI 2015). To combat inventory shrinkage from shoplifting, many retailers rely on the services of private security/loss prevention personnel (see ▶ "Retail Security: Use of Security Guards" chapter and ▶ "Security Guards: Authority and Power" chapter in this volume), loss prevention awareness and training, and antitheft devices (Moraca and Hollinger 2017). This chapter focuses on describing shoplifter demographics, motives, and methods, as well as legal responses for retailers and loss prevention agents who apprehend shoplifters.

Shoplifter Demographics

Retailers and their agents (e.g., clerks, private security officers, loss prevention personnel) attempt to differentiate potential and active shoplifters from nonoffending customers and to apprehend them during or subsequent to the commission of their crime. The most common strategy used is offender profiling, which relies on the typical demographics of offenders described in law enforcement apprehension reports (Shapiro and Maras 2017). Official arrest data indicate various characteristics, such as sex, age, and race/ethnicity, of those arrested for larceny theft. Shoplifting, however, is but one type of larceny theft, so the statistics reported include those arrested for other larceny-theft offenses (e.g., pick pocketing, purse snatching, bicycle theft), as long as stealing was not done by force or violence (FBI 2015).

The majority of juvenile and adult offenders arrested for larceny-theft offenses (57%) have been male (FBI 2015). According to the FBI (2016a, 2016b), juveniles were responsible for 13% of property crime offenses (6% at ages 10 to 12; 21% at ages 13 and 14; 20% at age 15; 25% at age 16; 28% at age 17) and adults 18 years and older (7% for ages 18–19; 18% for ages 20–24; 17% for ages 25–29; 14% for ages 30–34; 8% for ages 40–44; 7% for ages 45–49; 5% for ages 50–54; 4% for ages 55–59; 3% for ages 60 and up) were responsible for the remaining 87%. Race/ethnicity data indicated that the majority of juvenile larceny-theft offenders were European American (60%, only 13% identified as Latina/o), 36% were African American, 1.6% were Asian American, and 2% were from Native/Pacific Islander American (FBI 2016a). Similarly, adult larceny-theft offenders were predominantly European American (70%, only 14% identified as Latina/o), 27% were African American, 1% were Asian American, and 2% were from Native/Pacific Islander American (FBI 2016a). In summary, the demographic profile for larceny-theft offenders would be predominantly male and European American; as for age, juvenile offenders would likely be 15–17 years old, whereas adult offenders would likely be 20–34 years old.

Does this profile accurately represent shoplifters? The answer is probably not; if it did, there would be a high apprehension rate and low shrink rate from shoplifting. There are several problems with the database itself. Most importantly, the arrest dataset is too broad in that it is comprised of all larceny theft offenders and is unlikely to be a true representation of all shoplifters. As previously mentioned, the majority of shoplifters are simply not detected by retailers. Shoplifters steal on average between 48 and 150 times before being apprehended (Farrington 1999; Harnischmacher 2000, as cited in Hirtenlehner et al. 2014; NASP 2014a; Nelson and Perrone 2000; Williams et al. 1987).

Also missing from the arrest data are shoplifters apprehended by retailers who are not turned over to the police. Even when stores post a "notice of intent to prosecute shoplifting" sign, fewer than one-fourth of them are arrested and formally charged (Elliott 1995). According to Moraca and Hollinger (2017), the average number of shoplifter apprehensions declined from 3455 in 2015 to 3323 in 2016 to 1441 in 2017, despite a significant increase in the rate of shoplifting, which averaged a loss of $798.48 per incident in 2017 ($974 per incident for apparel).

The arrest data are also distorted (i.e., not inclusive of all apprehended shoplifters) due to police officers' use of discretion, which allows them not to charge some offenders (e.g., because of age, criminal history, merchandise cost); instead, offenders are released with a warning, resulting in only a small proportion of all shoplifters who are actually booked (Dabney et al. 2004). Further, the average number of shoplifting cases prosecuted has declined over a 3-year period from 2739 in 2015 to 1935 in 2016 to 742 in 2017 (Moraca and Hollinger 2017). Researchers estimate that 1/5 to 1/3 of shoplifting offenders are not included in the FBI system (e.g., fingerprints) nor charged with each index offense, often leading to increased differences in recorded demographics, particularly for race and age (Elliott 1995).

Official arrest statistics are also a reflection of societal stereotypes and prejudices in regard to the typical criminal. These biases affect the retailers and their agents' decisions of whom to surveille, typically those who fit the physical appearance of a "criminal" stereotype (i.e., male, African-American, lower-class) profile, and whether or not the shoplifter gets processed, charged, and sentenced in the criminal justice system (Dabney et al. 2004; Shapiro and Maras 2017). In this way, the official profile is reinforced, despite the fact that shrink continues to increase. By limiting their scope, retailers are actually allowing shoplifters who do not fit the stereotype to steal without threat of apprehension (Shapiro and Maras 2017). The impact of stereotypes becomes apparent when retailers and their agents target potential shoplifters from groups that are out-of-sync with their representation in the population. Differential surveillance practices due to consumer racial profiling result in a higher number of African American shoplifters being arrested than are actually represented in the population (Dabney et al. 2004). The result is often harmful to the reputation of the store, reduction in minority shoppers, and lawsuits, without effectively reducing shoplifting incident rates (Shapiro and Maras 2017).

To understand who the shoplifter really is, retailers must consider information from a number of sources. Research findings examining the public's criminal stereotypes have been mixed, as some believed shoplifters to be usually female (Dabney et al. 2004) and others usually male (Shapiro and Maras 2017). Self-report data indicated that boys/men and girls/women from a variety of ethnic/racial backgrounds shoplifted equally (Elliott 1995; NASP 2014a). However, the official rate of 57% of men that were arrested for larceny-theft (FBI 2015) was suspicious as it was higher than their representation in the population, which according to the 2016 US Consensus was estimated as 49% (Pew Research Center 2018). Similarly, arrest and imprisonment of juvenile and adult minority offenders for larceny, particularly African Americans (36% and 27%, respectively) and Native/Pacific Islander Americans (2%, each), demonstrate disproportionate treatment in comparison to their representation in the population. According to the US Census for 2016, estimated proportions of citizens were 13% African American descent and 0.8% Native American/Pacific Islander American (Pew Research Center 2018). In summary, given the spontaneity of shoplifting incidents, the proportions of sex, age, and ethnicity/race should reflect the population in that area and region of the country. To best understand the common demographics of the common shoplifter for their stores, retailers must examine the demographics of their customer base, allowing for the probability that anyone may shoplift.

Motives of Shoplifters

The majority of children (72%) and adults (73%) who shoplifted indicated that they did so spontaneously (Gold and Lang 2012; NASP 2014a).

Shoplifters have a variety of motives for stealing, but the perception that the act is low risk facilitates and maintains the behavior (Tonglet 2002). Both juvenile and adult shoplifters steal for financial reasons, obtaining items that they could not otherwise afford, usually luxury products rather than basic necessities. Some shoplifters are involved in organized criminal gangs and their "job" is to steal a list of items for the sole purpose of resale or profit (NASP 2014a). Peer pressure is another motivation, particularly for youth who may be required to show they can be brave or loyal to their friends or gangs. Another motive is emotional (NASP 2014a), particularly when shoplifters receive an emotional boost or thrill from successfully stealing (i.e., obtaining merchandise without getting caught by loss prevention agents). Others engage in shoplifting to support their substance abuse addictions or because they have psychological or mental health disorders, such as depression or kleptomania, an impulse disorder (NASP 2014c). Even when caught, shoplifters may engage in rationalization and neutralization to reduce their moral responsibility for the crime (Cromwell and Thurman 2003).

Typical Methods for Shoplifting

Retail and loss prevention personnel should learn which behaviors are typically exhibited by shoplifters as a means for discerning them from shoppers. Specifically, juveniles and adults who intend to steal will often exhibit signs of nervousness (e.g., facial grimaces, eye darting, lip and/or nail biting, shoulder tension), pick up merchandise, then look around to determine the location of cameras and staff, and bring items to remote areas of the store (Dabney et al. 2004). They choose busy, peak times to commit their theft knowing that it is more difficult for clerks to detect them or distinguish them from shoppers. Shoplifters may even purchase some items to avoid suspicion or, if caught, to appear to be the "absent-minded" shopper.

There are three main methods – concealment, grab-and-escape, and price/electronic tag tampering – used by shoplifters to steal items. Shoplifters commonly use concealment as their means to steal (Dabney et al. 2004). Potential shoplifters will enter stores with empty bags, containers, and even strollers or wear bulky clothing that may even be out of sync with the weather, all of which can be used to hide merchandise (Dabney et al. 2004). Although shoplifters do work alone, more often they work in pairs or groups. One member serves as a distracter, engaging the sales staff in various ways such as requesting they retrieve an item from the back of the store or by asking questions, while the other member or members steal merchandise on the sales floor or by taking it inside the dressing room where they conceal it within another container, such as a bag, or on themselves, such as under their clothes or coat (Dabney et al. 2004). Shoplifters may be accompanied by young children who serve as a distractor or whose strollers or carriages provide an area to conceal items. This technique provides plausible deniability for shoplifter-parents as they can blame the child for taking the items or indicate that they placed items inside while caring for the child and then forgot about them. Another method, grab-and-escape, involves a person or a group of people rushing in, grabbing one or more items, and then running out of the door. Stealing is also accomplished by switching high price tags with low prices tags, removing electronic tags, and/or by returning stolen items for a refund. According to Moraca and Hollinger (2017), fraudulent returns averaged $1766 for all retail ($969 for retail apparel).

Retailer Responses to Shoplifting Within the Law

The states allow retailers and their agents who have "probable" or "reasonable" cause to invoke "merchant's privilege" to detain a suspected shoplifter (International Association of Professional Security Consultants/IAPSC 2015, pp. 2–3; Nemeth 2018, p. 187; also see ▶ "Investigations: Criminal" chapter in this volume). Consistent with the definition of retail theft offense, the agent must witness the suspect approach merchandise offered for sale, stored, or on display;

take it (i.e., be in possession of it); and intentionally deprive the owner of it by (willfully) carrying it away, concealing it, converting it, or failing to pay for it (IAPSC 2015, p. 3; Nemeth 2018, p. 171; see also ▶ "Investigations: Consumer Retail Shoplifting" in this volume). Conversion is the process of retail theft by which a person alters the price of merchandise or renders the inventory control tag on it inoperable by destruction or removal (Nemeth 2018, p. 171).

Agents must have firsthand knowledge for misdemeanor offenses (i.e., directly observe) and reasonable grounds for felony offenses that the suspect took and failed to pay for the merchandise (Nemeth 2018, p. 188). An agent may make a "citizen's arrest" – but only if the agent witnessed a misdemeanor crime or when the agent is informed and is certain that a felony crime occurred (Nemeth 2018, p. 187). Agents should identify themselves upon approach of the suspect and present credentials while acting in a professional and calm manner. Most states allow agents to detain the suspect upon concealment of the unpurchased merchandise, whereas some states require that the suspect leave the store (IAPSC 2015). In the latter case, the suspect should be asked to return the merchandise and then accompany the agent back to the store (IAPSC 2015). When processing suspects, agents should ensure their safety from hidden weapons by separating suspects from their bags and, when necessary, perform a "Terry-style" pat-down (Nemeth 2018, p. 187).

There is limited civil liability protection when a suspect is detained for a limited amount of time by an agent who has a reasonable suspicion of shoplifting in order to investigate the merchandise theft, recover it, and summon the police (Budden 1999; IAPSC 2015, p. 4). These "Merchant statutes" allow agents to search for unpaid merchandise inside suspects' possessions, such as their bags or baby strollers, but does not allow them to conduct a search of the person's body or clothing (Budden 1999). A best practice approach is recommended to reduce the likelihood of successful civil liability suits against the retailer and agents (IAPSC 2015). According to IAPSC (2015), the agent should: (a) approach and use nonthreatening language and actions towards the suspected shoplifters; and (b) avoid physical handling of the suspect, limiting use to minimal force only for restraining someone from fleeing, except when bystanders are nearby or when against store policy (i.e., no touch, no chase), in which case agents should call the police. Even when the police are not involved, it is important that agents make an in-house loss prevention report that provides important information regarding the shoplifter's demographics, itemizes the stolen items and costs, identifies witnesses, and includes a narrative of what happened. Stolen merchandise should be photographed, logged, and stored for evidence if a court case is made or, if allowed, restocked.

After confirming that the suspect did indeed steal items from the store, retailers must decide whether to handle the shoplifting incident informally (aka catch-and-release), such as talking to the parents or through in-store sanctions (e.g., trespass agreement), or formally by turning the shoplifter over to the police or file civil damages (Gold and Lang 2012; NASP 2014b). The decision to process individual shoplifters formally by contacting the police for subsequent arrest and prosecution is a difficult one; retailers call the police for about half of all apprehensions, even though warnings of prosecution signs have been posted (NASP 2014a; Williams et al. 1987). Alternatively, retailers may use civil recovery by suing the offender for loss and damage of merchandise (Gold and Lang 2012). In contrast, shoplifters who part of an organized shop theft group, that is, those who have a list with items to be stolen that match the shoplifted items, should be turned over to police (Martinez 2005).

Retailers may seek compensation for expenses associated with the shoplifting incident and penalty damages, regardless of whether the items stolen were recovered undamaged (NASP 2014b). Ideally, retailers would prefer to eliminate or severely reduce shoplifting and the costs associated with it. A Canadian study in British Columbia showed that recidivism up to 2-years later was lower among shoplifters who completed a community-based restorative justice program supported by federal government funding than

those processed through the criminal justice system (e.g., Robinson et al. 2013). Of particular interest was recidivism for shoplifters with criminal histories: 70% of adult women and 88% of adult men who were charged reoffended versus 29% of women and 50% of men who completed the restorative justice program reoffended. There are restorative justice-themed diversion programs associated with American courts at public expense but only about one-fourth of them track recidivism as an indicator of success (Gold and Lang 2012).

Beginning in 2011, merchants in the United States (e.g., Walmart, DSW, Bloomingdales, Burlington, Decathlon, Kroger) offered offenders the choice of arrest or to pay for a shoplifting restorative justice education course, such as one offered and administered by Corrective Education Company, aimed at reducing recidivism (Rappaport forthcoming; Richey 2016). The benefits were threefold as retailers were not financially responsible for the course fee and did not have to contact and provide evidence to law enforcement; offenders were kept out of the criminal justice system; and the community did not have to pay police and court fees associated with shoplifting offenses (Rappaport 2018). However, the recidivism rates were less clear as only the for-profit agency evaluated the data. This company was involved in a recent summary judgment, *People v. Corrective Education Company* et al. (2017), in which the Court ruled that forcing shoplifters to watch the video of the restorative justice program and then to choose between criminal prosecution or paying for the program amounted to false imprisonment and extortion. In the wake of this decision, a RICO class action law suit was filed on April of 2018 with the Supreme Court (see Doe et al., v. Walmart Inc. 2018).

Conclusion

Retail shoplifting has a dramatic impact financially on society in a variety of ways. Clearly, the businesses that lose revenue through shoplifting are directly affected. However, there is an indirect, domino effect caused by shoplifting when retailers are forced to hire loss prevention staff and purchase antitheft security devices. Specifically, employees are laid off or have their wages reduced in order for companies to recover the cost of deterrence measures and make up for the loss of potential income and profit. Consumers are dually burdened by the increase in the cost of items and the inconvenience that the loss prevention techniques provide for shopping (Richey 2016). Additionally, local jurisdictions must absorb the cost of increasing law enforcement to arrest shoplifters and paying associated expenses from court cases for prosecutors to charge the shoplifters and for judges to hear the cases (NASP 2014a). Communities lose important revenue though commercial taxes on the items that were stolen instead of being purchased and on income taxes from stores when retailers move out of the neighborhood due to the high losses suffered from shoplifting (NASP 2014a). Store closings, in turn, increase unemployment for those in the affected areas, as well as impact the economic well-being of the nation.

Retail Security: Use of Security Guards

Kenneth J. Grossberger

Keywords
Security guard · Loss prevention · Shrinkage · Shoplifting · Organized retail crime (ORC)

Definition

Retail security is the protection of goods, personnel, and customers in the exchange of those assets in a store setting, a shopping mall, online, and in locations in the chain of supply that provides those goods and services.

Introduction

Security guards are a key protective component for the US retail industry, which had gross sales of about $3.8 trillion in 2019 (Young 2020; Digital 360 Commerce 2020). Security guards protect stores, malls, warehouses, and distributions centers, and they also control access, provide visible deterrence, protect customers and store staff, protect assets, conduct investigations, perform customer service tasks, and assist store management. Retail establishments have been using guards as a primary form of security for many years.

The Purpose of Retail Security

The two basic functions of retail security are loss prevention (LP) and safety. Security guards are responsible for both. Loss prevention is synonymous with asset protection (LP Magazine 2020), and retail security personnel are sometimes called asset protection officers or loss prevention specialists, depending on the assignment.

Loss Prevention

Loss prevention is a general term for controlling any kind of loss in a retail establishment (LP Magazine 2020). This also involves asset protection, which includes merchandise and products (the inventory), the store equipment and logistics, the computer and communication equipment, and the displays.

Safety

Security officers are also responsible for the safety of shoppers and staff and perform patrols and inspections in stores and other retail facilities. They also perform safety functions such as evacuations and fire drills.

Physical Security

The primary responsibility for retail security guards is to protect the stores. In addition, guards protect retail facilities such as malls, warehouses, and distribution centers. Guards are sometimes responsible for retail inventory, stock, deliveries, and transportation of retail goods. Physical security includes staff well-being, brand risk, and physical damage to retail facilities (Humphreys 2019).

Store Models

There are several different models of stores, and each presents different risks and challenges for security guards. There are numerous clothing stores including chain stores and individual local stores. There are also chain supermarkets, jewelry stores, pharmacies, "specialty" (stores that sell a variety of goods), department stores, drug stores, convenience stores, and discount stores (Bhasin 2018). Stores may be in outdoor malls, indoor malls, strip malls, commercial office buildings, commercial office parks city streets, and piers.

Security Guard Responsibilities and Posts

As in other venues, a security officer on post at a retail location is responsible for the basic functions of observe and report, post and patrol, as well as customer service (Spadanuta 2010; Purpura 2002). In addition, a guard acts as a visible deterrent against crime, including shoplifters and other would-be offenders (Dempsey 2010).

There are other security assignments in retail environments such as a loss prevention specialists who perform the basic security functions but who also may have responsibility for inventory (deliveries, counts, controls, and reporting), incident investigations, shoplifting, burglary, fire prevention, safety, organized retail crime (ORC, see below), coordination with mall or building security, and security incident statistics (Purpura 2002). Store detectives (SDs) patrol the interior of stores and make apprehensions if they spot

shoplifters and ORC boosters. Some other security guard responsibilities are to act as an undercover (UC), plain clothes agents (who usually do not make apprehensions as their mission is to report theft, fraud, and other illicit behavior), and to be responsible for such concerns as sweethearting (see below), inventory issues, credit card fraud, and other negative activity when observed. UCs remain anonymous because their exposure would minimize their effectiveness. Their reports go to senior retail company management for further action. Security personnel in retail locations are usually unarmed because the billing rates are cheaper and there is less liability. Armed posts are used in high crime areas and where there is money or other critical assets to be protected. Armed personnel are also used for events in stores where celebrities or models are present.

Post Orders and Uniforms

Post orders are an industry standard and are used as specific orders and instructions for security personnel on post and "are written instructions of activities that security officers are expected to perform and should be detailed and reflect expectations" (Seivold 2019). This may include the use of logbooks (paper and electronic) and how to make entries, methods of checking in and out, reporting incidents, attire and grooming, customer service standards, and emergencies procedures (including evacuation instructions).

Security personnel may wear a number of different kinds of uniforms. While the police style uniform was the standard for many years, more recently, public-facing retail establishments have been using soft look uniforms such as blazers and slacks with white shirts and ties. Security officers may wear patches on the blazers or have a security pin on their jacket pockets to identify as security. UCs, store detectives, and supervisors are usually in plainclothes so as to blend in with shoppers and hide their identities.

Security Personnel Management and Supervision

The management and supervision of security personnel in the retail environment is critical to the success of any security/safety program. Guards and other officers must be properly hired and vetted. For example, guards must be checked by means of the following: security license checks and fingerprinting, criminal records check, previous employment verification, background checks, drug tests, driving record checks, social security number verifications, proof of legal right to work, federal and state criminal record checks (pursuant to state requirements), personal reference checks, education verification, military service verification, and previous employment verification (Secure Community Network n.d.).

Officers must be trained in the following areas: entry security, observation techniques, shoplifting, ORC (see below), customer service, incident deescalation, emergency procedures, evacuations, the role and purpose of private security, professional attitude, communication skills, proper recording and reporting of events and incidents, civil liability, violation of policy and procedure, workplace diversity, and sexual harassment issues. Officers must also receive post-specific instructions. The purpose of training is to ensure the guard has "observable and measurable knowledge, skills, abilities, and personal attributes that contribute to enhanced employee performance and ultimately result in organizational success" (Kitteringham 2020).

Most US states have licensing requirements for security (SecurityGuard-License.org n.d.), and if unlicensed personnel are deployed, the potential liability is significant for both the security company and the retailer. For example, if there is an incident and the retailer is sued, the security company's general liability insurance policy covers this risk, but if the officer involved is not licensed, the insurance company may disclaim liability leaving both the security company and the retailer unprotected.

Security officers take several tests during their careers, and there are almost always state-mandated tests as part of the licensing process (SecurityGuard-License.org n.d.). Retests are usually taken upon license renewal. Officers, typically, have to take tests as part of the hiring process as well to see if they have sufficient knowledge to be a security officer. If there is

additional training, say for ORC or emergency procedures, there may be testing for these areas as well. If retail locations require professional certifications, for example, automatic external defibrillators and cardio-pulmonary resuscitation (AED/CPR), first aid, blood-borne pathogens, or fire guard, then that training requires testing as well (American Red Cross n.d.).

Similarly, supervising security personnel on duty at retail locations require industry knowledge and experience to support the officer and ensure that the store's post instructions are being followed. Security supervisors are on the ground, in retail locations, and face to face with security officers and customers. Their responsibilities are to the officer, the company they work for, or the store if there are proprietary personnel. Field supervisors are usually uniformed in such a way as to be identifiable as security, and may wear badges, patches, or pins to indicate this. Supervisors are response for "hiring, training, discipline, motivation, promoting and communicating" with security guards (Sennewald 2003).

Contract Versus Proprietary Security Guards

There are different models for security in retail, and the most significant is whether personnel are contract security (security companies) or proprietary security (in-house). Contract security guard sales were about $31 billion in 2018 (Mazareanu 2019), and such services were widely used. The security industry has many companies that provide security services to stores, malls, warehouses, and distribution centers. The larger retail companies with chain stores may have their own LP (or asset protection) departments, made up of executives, directors, regional managers, loss prevention investigators, and specialty personnel (such as ORC investigators or undercover agents). The responsibility is the same, whether a store uses contract security or its own personnel, and in many cases, stores used a mixed model with both contract security and their own asset protection staff. The LP departments for retail companies typically hire contract security personnel for entry security, interior patrol, store detective assignments, and loss prevention specialists, while proprietary staff handle management and specialty assignments. The main reasons for using contact security are that it is usually less expensive and security companies provide insurance coverage for the retail company. The client (the retail company) becomes an "additional insured" on the security company's general liability policy, meaning that the security company's insurance company accepts the liability of the client (Kagan 2020). These are strong incentives to use contract security as opposed to in-house personnel. The decision to spend money on contract security depends on shrinkage, store sales, and other risk factors. For example, if a store has high shrinkage but high sales, there is the need and the budget to hire contract security. But if store sales are low, the management's decision may be to not hire security even of the shrinkage is high. There may be risk factors that increase the need for security guards such as crime in the mall or the surrounding area. Guards are often hired to provide protection for store employees.

Mall security typically does not have responsibility for security in the stores themselves due to the liability of acting in a leased area where mall security is not specifically allowed, and also because there may be store proprietary guards on site (especially for chain stores) that is contracted for the security function. Conversely, store security typically has no responsibility for the mall areas as an officer assigned to a store must protect that venue and not leave the store if there is a problem somewhere else in the mall. However, store security often works with mall security on evacuations, events (e.g., holidays), and if security incidents occur (e.g., sharing of evidence, interviewing witnesses). There are many such opportunities for store security to interact with mall security.

Inventory and Shrinkage

Inventory is defined as "goods available for sale and raw materials used to produce goods available for sale" (Kenton 2019). Inventory represents the most important asset to be secured and also presents the greatest risk in retail security. Protection is required as the "turnover of inventory represents one of the primary sources of revenue generation" (Kenton 2019).

Shrinkage is defined as the difference between inventory and what got sold, or "loss of inventory related to theft, shoplifting, error, or fraud" (McCue 2019). In addition, there may be internal theft, damaged garments, credit card and gift card fraud, missed markdowns, or other inventory issues. Missed markdowns occur when goods that were reduced in price for a period of time are not increased back to the original price. Such errors cost the nongrocery retail industry over $300 billion in 2018 and were due, in part, to "inventory misjudgments" (Garcia 2019). In stores that sell equipment, there might be damage or vandalism (rendering it unsaleable). In food stores, there may be spillage, spoilage, and product being eaten (both by shoppers and staff), which reduce sales. Another factor is a store associate's employee discount abuse, where some shoppers get a break in the price due to an error, sweethearting (see below), or theft for payoff (e.g., a shopper gets a $20 price reduction and gives $10 back to the associate).

A major risk factor in assessing shrinkage is the cashiers at checkout. Even with all the technology such as electronic cash registers, CCTV systems, data systems that monitor cash and credit sales and Exception Based Reporting (or EBR, which finds "exceptions" to the normal patterns of sales so that LP personnel can focus on potential fraud and is defined as "a method of data analysis that compares an incoming stream of data to an established base set of data and flags items that don't quite match up," EBR-Group.net n.d.), the point of sale (POS) is still one of the biggest liabilities for a retail establishment. There is a great deal for a cashier to do: check out the merchandise, take the payment (cash, credit/debit card, gift card, store card, and credit voucher), process an exchange of items, answer customers' questions, and watch for shoplifting (Resume Resource n.d.). One risk in stores where shopping carts are used is to miss items in the "bottom of the basket" (BOB) which results in an unpaid merchandise (Progressive Grocer 2006). Store security can assist cashiers at high volume times and watch for these risks, or deter them, and UCs can check cashiers and report theft and fraud. All these factors contribute to shrinkage. There are other transactions that contribute to shrinkage such as credit card fraud (a federal offense), gift card scams (the use of phony gift cards supposedly issued by the store), price tag switching, and return item fraud (trying to return an item for credit that was not purchased) (Sennewald and Christman 2008).

Security guards, loss prevention specialists, UCs, and store detectives have a direct effect on reducing shrinkage. By effectively controlling store entry, observing store staff, patrolling the store, using security technology, making apprehensions, and using other techniques, store security may deter theft and reduce losses.

The retail industry annual shrink rate was 1.38% in 2018 (National Retail Federation 2020), which is comparable for previous years. But, that amounts to losses of over $52 billion. While there is a variety of technical means to reduce shrinkage, security guards and other forms of organic security are primary defenses in the protection of retail establishments. Internal losses in a store (including employee theft, inventory issues, and product damage) account for about 60% of the total (McCue 2019). Other losses come from shoplifting, ORC (see below), chain of supply issues (see below), and other factors (McCue 2019). The calculus by industry executives takes these data into account when considering budgets for security guards and other loss prevention personnel.

Theft Techniques

Shoplifting

One of the key factors in store loses is shoplifting, which comes in several forms from amateurs to professionals (Purpura 2002). There are shoplifters who shoplift often, the frequent flyers, either as a means of supplementing their income or to get free goods. There are the so-called casual shoplifters, who steal items occasionally in order to create their own discounts. Then there is the once in a lifetime shoplifter, who never stole anything before. The professional shoplifters may work in teams or alone but are associated with criminal organizations, and this falls under the

heading of organized retails crime (ORC), more on this below. Security uses the techniques mentioned above for deterring, spotting, and apprehending shoplifters. The means by which shoplifting is dealt with depends on store policy as some retailers are more aggressive about security (apprehensions) and others are more concerned with the guest experience and are less inclined to confront thieves in order to avoid physical incidents in the store that might disturb patrons.

Sweethearting

Sweethearting is a technique used by thieves to compromise a member of the sales team or the cashier. This is done by the thief being friendly to the team member in order to get a discount get something for free, or to distract that team member while an associate steals something (Hollinger 2018). UCs and LP personnel can spot such activity and deter it or make apprehensions as needed, and in accordance with the post orders.

The Robin Hood Effect

One source of loss occurs when employees try to help patrons they think are in need. This comes in the form of free or discounted merchandise, extended sales, or military or specialty discounts extended to nonqualifying shoppers. While these actions come from "good intentions and a desire to help others," they have a "significant impact on the bottom-line" (Penizotto 2020). A loss prevention specialist may be charged with the responsibility to monitor or stop this behavior or report it as dictated by store policy. The effect, coming from the perception of taking from the rich and giving to the poor, is that the behavior is justified as the company has a lot of money and the shopper is needy (Penizotto 2020). Undercover agents can be trained to spot this activity and to report it as necessary.

Organized Retail Crime

Organized retail crime (ORC) "involves the large-scale theft of everyday consumer items" (Finklea 2012) and groups of thieves. The typical ORC organization involves a street team comprised of a thief (the booster), the lookout (the spotter), and a "distractor" whose job it is to draw attention away from booster. Once the goods are removed from the store, the team sells them to Level I fence, who hired the team to take the product. The goods are then sold to a Level II fence, who repackages the goods and transfers them to a Level III fence, who resells them to an unsuspecting public. Not all ORC teams are this elaborate, as one may involve just a booster and a fence. This is a serious crime that costs retailers (and ultimately consumers) tens of billions of dollars each year (The Loss Prevention Foundation 2018). ORC teams typically look for expensive, portable goods in high demand as they are more profitable to steal and more moved and resold.

To combat this, Congress passed the Organized Retail Crime Act of 2008, which made ORC a federal offense, presumed to be a deterrent (Congress.gov 2008). The risks to stores are severe as sales are lost, brands are at risk (name products illegally resold may be damaged, compromised, not warranted, or in poor condition) or contaminated as in the cases of analgesics, baby food, and supplements (The Loss Prevention Foundation 2018).

Retailers provide specific training for this risk for loss prevention teams, store detectives, UCs, security guards, and store staff, so that ORC teams can be detected, deterred, or apprehended.

Audits and Investigations

Security guards and loss prevention specialist conduct audits and investigations, depending in the retail chain, the security contract, and the post orders (Purpura 2002). Investigations may be done on a scheduled or random basis. Audits are typically scheduled and are usually for inventory purposes. For example, a large shipment may be delivered to a store or distribution center and security may conduct an audit to ensure the count of the goods is correct.

Chain of Supply

Security personnel are also responsible for protecting many parts in the retail chain of supply including manufacturing facilities, warehouses,

distribution center, and transportation nodes (trains, depots, airports, trucking, etc.). Security controls access for both staff and vehicles, conduct inventories, do patrols, do safety checks, and conduct drills and evacuations at these facilities. However, technology and growing customer demands have changed this as the "supply chain is not just about distribution and transportation. . .. today's retailers have extensive networks that enable companies to monitor and ensure quality" from retailer to customer (Bandaranayake 2019). This puts additional pressure on security to ensure the safety of goods as they move through the chain in a reliable fashion.

Safety

Security officers are also often responsible for safety in a retail environment as part of an overall risk management program, as "safety is a major loss prevention measure to reduce the likelihood of accidents and injuries" (Purpura 2002). Such a program usually covers risk conditions such as accidents, fire safety, evacuations, active shooter, bomb incidents, workplace violence, safety incidents such as accidents and medical incidents, storms, floods, hurricanes, earthquakes civil disturbances, and power outages. Security personnel are trained to deal with and report such events and to work in coordination with first responders, law enforcement, other businesses in the area, and the community.

Conclusion: The Evolution of Retail Security

The future of retail security looks to combined systems and security personnel with expanded CCTV and alarm systems, robotics, and geo-fencing (electronic attendance systems) for tracking and reporting. Security personnel in retail establishments will be better trained in more sophisticated techniques as technology advances and thieves become more sophisticated in their methods.

Definition

Risk and risk analysis: According to the International Organization for Standardization (ISO 31000: 2009), risk is "the effect of uncertainty on objectives," and risk analysis is "the process to comprehend the nature of risk and to determine the level of risk." Simply put, risk analysis involves understanding the possibilities of risk and the ability to measure their level in relation to an organization's objectives.

Introduction

In this ever-changing and complex world, the threat landscape continues to evolve. With the myriad of natural and human-made threats, organizations must be aware of the threat landscape and the frequency and impacts these threats present. Additionally, the concept of risk is also essential to consider and address as each threat

presents a measure of risk. As stated in the definition above, it is the analysis of risk which allows organizations the ability to meet organizational objectives. In summary, organizations, both large and small, have business objectives to achieve, and to help fulfill those objectives, it is vital to understand the threat landscape and, therefore, proactively conduct a risk analysis.

Completing a risk analysis to assess an organization's current level of risk maturity can no longer be viewed as a trivial or cursory initiative. With more robust financial, operational, and regulatory requirements present, organizations are mandated to conduct comprehensive risks analysis efforts and, in some cases, implement a risk management process and program, which continually monitor, assess, and report on risks to the organization. When first starting a formal risk analysis process and program, an organization can leverage a framework that includes a well-defined set of standards to follow. Assisting in this endeavor, national and international standards for risk analysis, encompassed within risk management, help organizations of all sizes within all industries.

The objective of this entry is to introduce and articulate national and international standards regarding risk analysis. With this introduction to national and international standards, organizations will learn the component which defines risk analysis as well as the underlying principles, framework, and process.

Risk analysis, risk assessment, and risk management are used interchangeably within the industry, yet within the standards, risk analysis is one aspect of risk management. In 1970, the International Organization for Standardization (ISO) began publishing international standards so that they could be adopted nationally (Epstein and Timmermans 2010). ISO is an independent, nongovernmental international organization that creates international standards developed by experts from its 164 countries or member nations (ISO 2015). The standards are intended to be a solution for potential challenges which governments, private industry, and the public may face (ISO 2015). ISO is the "largest international developer and publisher of international standards" and is coordinated by a Central Secretariat based in Geneva, Switzerland (Gjerdrum 2018).

Global-centric, there are 120 member bodies, 40 correspondent members, and 4 subscriber members of ISO. Each nation has one member, and the full member bodies "influence ISO standards development and strategy by participating and voting in ISO technical and policy meetings" (ISO n.d.). A trusted source, ISO has published more than 21,000 standards (Graz and Hauert 2019).

According to ISO, standards are reviewed every 5 years. They are edited by technical experts who are nominated by ISO's members. These experts form technical committees that are responsible for a specific area of expertise (ISO 2015).

It is important to note that ISO is considered the authoritative institute for standards and that many countries adopt or model the ISO standard as their national standard.

In addition to 31000: 2018 Risk Management, ISO/ TC 262 has developed "ISO/TR 310004: 2013 Risk Management – Guidance for the Implementation of ISO 31000" and "IEC 31010: 2009, Risk management – Risk assessment techniques" (ISO n.d.). ISO 31000 Risk Management is, intentionally, a broad standard, as opposed to specific, in order to ensure that "the needs of any type of organization or situation" are met (Lalonde and Boiral 2012).

In order to remain current and advance standards like risk management, there are many meetings, drafts, and inputs given to reach consensus, over a 3-year period typically (Esposito 2017). The standards are reviewed and published again every 5 years (Esposito 2017). This rigorous evaluation and updating from industry experts and member nations keeps the standards current and in line with the most recent developments in all aspects of risk management and risk analysis.

The American National Standards Institute (ANSI) is a national organization. It adopts international ISO standards and authorizes US participation in the standards-making process (Gjerdrum 2018). Technical Advisory Groups (TAG) are also formed within ISO. The American Society of Safety Professionals (ASSP), a US leader in the development of risk management and risk analysis best practices, is the secretary to this TAG

group of experts, in the United States, who participate in the ISO 31000 standards-making process (Gjerdrum 2018). At the national and international levels, governmental, academic, and industry interests are broadly represented.

ANSI provides a significant benefit to organizations with the standardization of new and emerging technologies. As new standards are introduced, organizations as well as government agencies can create products and services to meet or exceed the ANSI standards. For example, the standardization services that ANSI provides help to ensure that computer manufacturers build components which will be compatible with other third-party components. The process by which a new standard is accredited by ANSI is a rigorous one and helps to ensure that both consumers and manufacturers are presented with a standard that has passed stringent guidelines. This is important as industry standards help ensure a level of uniformity across technology which provides a measure of risk mitigation.

National Standards Related to Risk Management

In 2011, the ISO 31000 standard was published as ANSI 690.2 in the United States (Esposito 2017). Recognizing the precision and completeness of the international standard, the United States adapted it without any modification. The national ANSI 690.2 standard's approach to the risk management principles, framework, and process follows the approach put forth by ISO 31000:2009.

International Standards Related to Risk Management

ISO 31000

An organization protects and creates value by successfully managing risk (Gjerdrum 2018). In pursuit of an organization's goals and objectives, it is paramount to have a shared understanding of risk management (Gjerdrum 2018). This includes the ability to identify risks across all operations; knowing when it is appropriate to undertake risk; knowing who is in the best position to manage specific risks; and knowing which people are accountable for risk (Gjerdrum 2018). All organizations face factors and influences that jeopardize whether it will achieve its objectives – some risks are external and some are internal (Gjerdrum 2018). Risk management supports the achievement and organizational objectives by understanding those uncertainties and managing their effects upon the organization and its operations (Gjerdrum 2018). Organizations manage risk in order to protect or preserve value: maintain public trust; protect people and assets; and to focus on the cost of risk (Gjerdrum 2018).

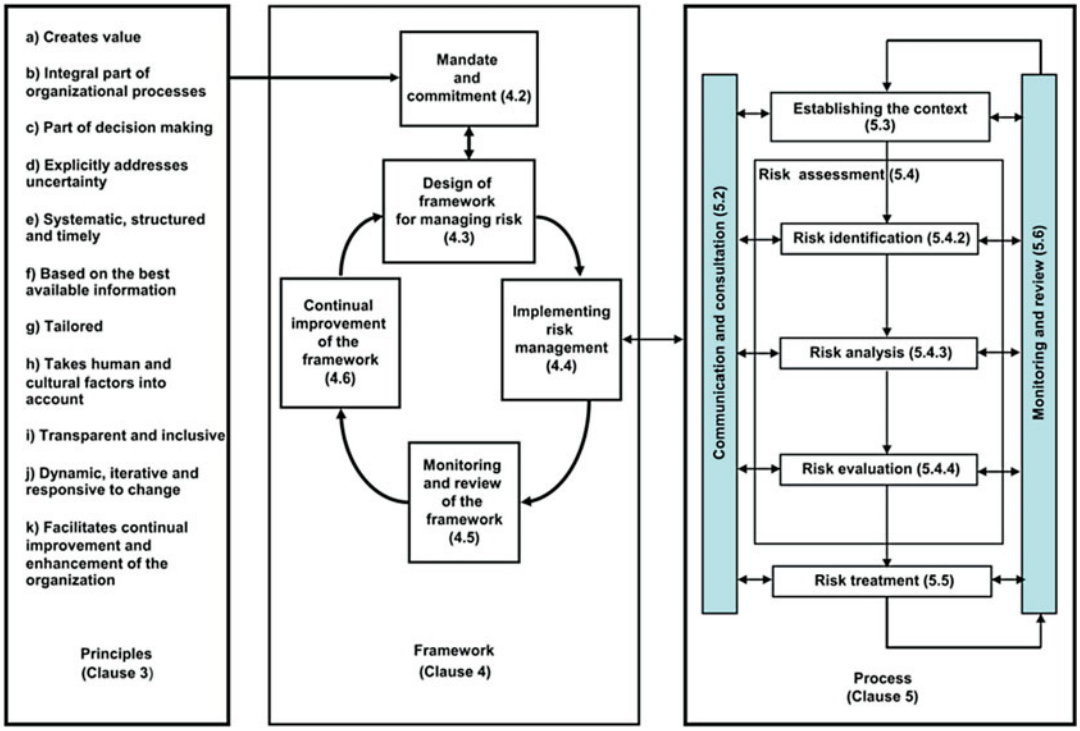
ISO 31000 is a general standard, intended to address all types of challenges, including "threats to the environment, public health and food safety issues, threats to critical infrastructure, hazards presented by certain products, and interruption of the supply chain" (Lalonde and Boiral 2012). This standard can be used by any industry, sector, or profession: security, IT or fire risk assessment; corporate, military, emergency, storms, business interruptions, oil wells, police, and even personal risk (Esposito 2017).

ISO 31000 encourages consideration of what you may already have in place for risk management and how to more fully coordinate and integrate that effort. The focus in ISO 31000 is to manage risk in relation to the mission and objectives of an organization. Risk management supports taking risks and good decision-making. In the United States, the term "Enterprise Risk Management" (ERM) is used, and although it is different than the international verbiage, they are, in practice, the same thing (Gjerdrum 2018).

ISO 31000:2009

Based on a standard which Australia and New Zealand developed called AS/NZS 4360, the ISO 31000: 2009 Risk Management Standard is an international guideline. Over 60 countries have adopted it as their national risk management standard (Hutchings 2016).

There are three distinct parts which form the standard for risk management: the Principles, Framework, and Process as seen in Fig. 1 as Clause 3, Clause 4, and Clause 5. Further, the



a) Creates value
b) Integral part of organizational processes
c) Part of decision making
d) Explicitly addresses uncertainty
e) Systematic, structured and timely
f) Based on the best available information
g) Tailored
h) Takes human and cultural factors into account
i) Transparent and inclusive
j) Dynamic, iterative and responsive to change
k) Facilitates continual improvement and enhancement of the organization
Principles (Clause 3)
Mandate and commitment (4.2)
Design of framework for managing risk (4.3)
Implementing risk management (4.4)
Monitoring and review of the framework (4.5)
Continual improvement of the framework (4.6)
Framework (Clause 4)
Communication and consultation (5.2)
Establishing the context (5.3)
Risk assessment (5.4)
Risk identification (5.4.2)
Risk analysis (5.4.3)
Risk evaluation (5.4.4)
Risk treatment (5.5)
Monitoring and review (5.6)
Process (Clause 5)

Risk Analysis: National and International Standards, Fig. 1 ISO 31000: 2009 Risk Management-principles (ISO 2009)

ISO 31000 Risk Management Standard is used as a reference for many ISO families of standards (Hutchings 2016).

Principles

The risk management principles (Clause 3, Fig. 1) of ISO 31000 provide the "foundation of the work and describe the qualities of effective risk management" (Gjerdrum 2018). According to Esposito (2017), this is "why" we engage with risk management. As seen in the first box to the left in Fig. 1, ISO 31000: 2009 revolves around 11 principles of risk management that can be customized. By design, these principles remain flexible so they can fit any organizational context. A plan for risk management does the following (ISO 2009):

(a) Creates value
(b) [Is an] Integral part of organizational processes
(c) [Plays] part in decision-making
(d) Explicitly addresses uncertainty
(e) [Is] systematic, structured, and timely
(f) [Is] based on the best available information
(g) [Is] tailored
(h) Takes human and cultural factors into account
(i) [Is] transparent and inclusive
(j) [Is] dynamic, iterative, and responsive to changes
(k) Facilitates continual improvement and enhancement of the organization

These principles serve as a guideline or foundation for an effective risk management framework and process, which may be used with any service or product (Hutchings 2016).

Framework

The risk management principles (listed above a–k) are then translated into a risk management "framework" as seen in the middle box (Clause 4) of Fig. 1 (Esposito 2017). What is included in one's organizational written plan regarding risk management would address each of the five smaller boxes in the framework: "4.2 Mandate and

commitment, 4.3 Design of framework for managing risk, 4.4 Implementing risk management, 4.5 Monitoring and review of the framework and 4.6 Continual improvement of the framework" (ISO 2009). The risk management framework exemplifies "what" needs to be done to effectively engage in risk management. The following is a brief explanation of each component of the "framework."

4.2 Mandate and Commitment. The possibility that risk management may be mandated by a regulatory or governmental body needs to be considered. If there is leadership commitment within an organization, that commitment must be defined.

4.3 Design of Framework for Managing Risk. Outlining the organizational framework is crucial. This includes identifying who will be assessing and maintaining any suggested action plans, sharing relevant data, and deciding how often that data will be made public (Esposito 2017).

4.4 Implementing Risk Management. Determining the persons who possess the skill set needed to implement the risk management is paramount (Esposito 2017).

4.5 Monitoring and Review of the Framework. Ongoing monitoring and review of the framework must occur, and, if necessary, inspections and review of the steps involved are made (Esposito 2017).

4.6 Continual Improvement of the Framework. Finally, implementing an audit process to review and improve the risk management process every couple of years is recommended as a best practice (Esposito 2017).

The risk management framework provides for "consistent integration across the organization" and is likened to a "big picture integration" (Gjerdrum 2018). It is iterative in nature and fluid, as demonstrated by the arrows in the clockwise sequence.

Process

According to Esposito (2017), the risk management process (Clause 5), in the right box of Fig. 1, is "how" you engage in risk management. It can be viewed as the "steps taken to "evaluate and review risks," whether they are individual or in a portfolio (Gjerdrum 2018). As described in the previous section, the principles of risk management influence how an organization implements the risk management process (Gjerdrum 2018). The risk management process includes the following, which will be explored: "5.2 Communication and Consultation; 5.3 Establishing the Context; 5.4 Risk Assessment (including 5.4.2 Risk Identification, 5.4.3 Risk Analysis, and 5.4.4 Risk Evaluation); 5.5 Risk Treatment; and 5.6 Monitoring and Review" (ISO 2009).

5.2 Communication and Consultation. A key component for stakeholder "buy-in" is their involvement in the development of a treatment plan. Communication and consultation with all interested parties is essential: stakeholders, employees, and management (Esposito 2017).

5.3 Establishing the Context. Definitions for each item in this box must be set, and ascertaining how the organization will meet its objectives is key (Esposito 2017). Identification of the external and internal parameters that are considered when looking at risk management is also vital (Esposito 2017). This can be regulatory or legislative, for example.

5.4 Risk Assessment. Risk assessment occurs when there is 5.4.1 Risk Identification, 5.4.2 Risk Analysis, and 5.4.3 Risk Evaluation.

5.4.1 Risk Identification The risk identification process which the organization or situation utilizes must be determined (Esposito 2017). A survey of how an organization analyzes risk to identify the hazards and hazardous situations or events is needed (Esposito 2017). Some examples of methods used for risk identification are brainstorming; look-up methods like checklists or hazard analysis which are common in the United States; scenario analysis like "what if"; and controls' methods where the control is studied to see if risk is truly mitigated by its use (Esposito 2017).

5.4.2 Risk Analysis Risk analysis informs the decision of which risks are worth pursuing and which should be avoided (Sadgrove 2016). Some other factors that need consideration are the matrix that will be used, the definition of likelihood, and the potential consequences (Esposito 2017).

Risk is then evaluated to determine whether enough is being done to manage the risk (Gjerdrum 2018). If not, then you consider the next box (Clause 5 in Fig. 1), risk treatment. In risk treatment, some risks may be worth supporting, and in other situations, there may be considerations of how to minimize the threat (Gjerdrum 2018). This is discussed in further detail in the Best Practices section (see Fig. 6).

5.4.3 Risk Evaluation The ability to determine what level of risk is acceptable or tolerable is called risk evaluation. Controls are selected to test risk level and help decide if additional treatment may be necessary. This is one step that is often overlooked, but it is a best practice, often taking place as compliance or an industry practice (Esposito 2017). You may have reduced the likelihood of a risk, but you have not reduced its potential severity unless there is an evaluation of controls (Esposito 2017).

According to Esposito (2017), the most preferred and reliable controls to the least are as follows:

(a) "Risk avoidance
(b) Elimination
(c) Substitution
(d) Engineering controls/safety devices
(e) Warning
(f) Administrative controls (e.g., in work, supervision, training)
(g) Personal protective equipment (PPE)"

Most people do their first risk assessment by utilizing these controls. The risk is identified, analyzed, and evaluated (Esposito 2017).

5.5 Risk Treatment. Once a risk is identified, management then decides how much funding will be allocated toward treating that risk (Esposito 2017). A treatment plan may include documenting proposed actions; assigning responsibilities, resources, and performance measures; reporting and monitoring; and timing (Esposito 2017).

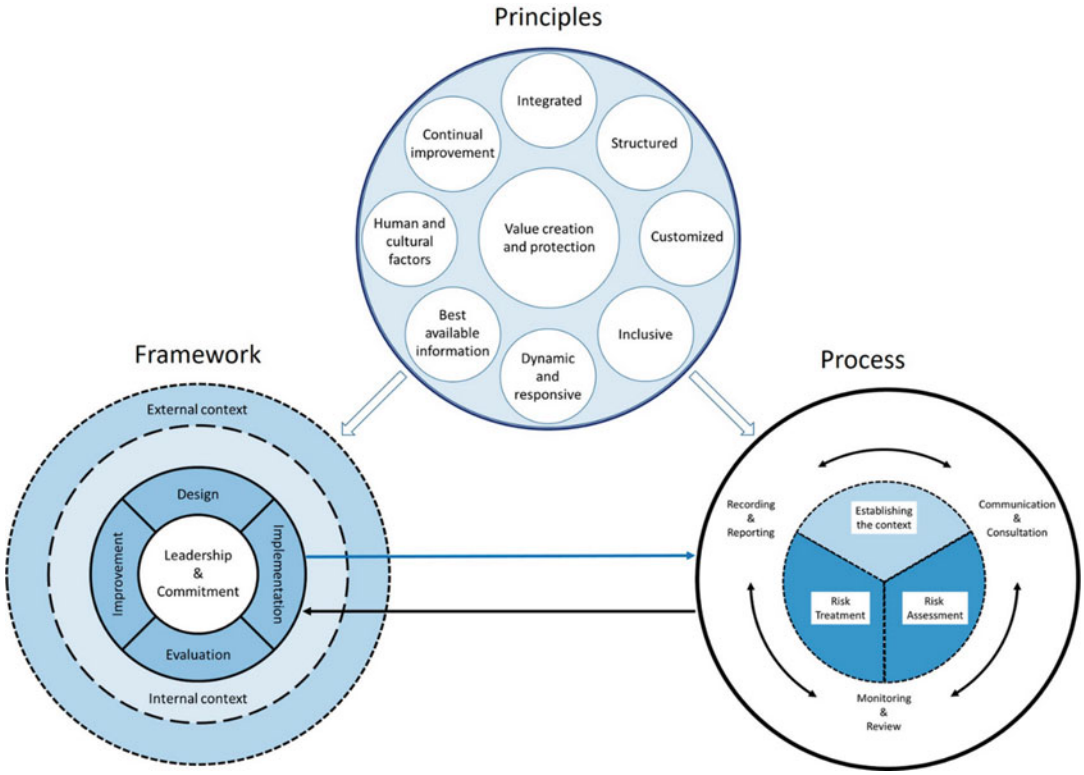
5.6 Monitoring and Review. The person or department that will monitor and review, as well as the person who shares any data or updates, must be established (Esposito 2017). Before ISO 31000: 2009, traditional risk management administration was perceived as a "department of no" (Gjerdrum 2018). The focus of risk management was on preventing and transferring risk because risk was generally perceived as bad (Gjerdrum 2018). With ISO 31000, however, risk owners are engaged to manage risks and risk is perceived as either good **or** bad (Gjerdrum 2018). Risk-taking and good decision-making are supported by the ISO 31000 Risk Management Standards, and the focus is on risk in relation to the organizational mission and objectives (Gjerdrum 2018).

Risk Management: Changes in Policy and Procedures

ISO 31000:2017 (e), Draft of ISO 31000:2018

Five years after the ISO 31000: 2009 publication, work began on its revision in 2014 by the ISO Technical Committee (TC) 262 (Gjerdrum 2018). There was a move away from jargon so that its language and concepts would be more accessible to all readers and organizations (Gjerdrum 2018). Of note were the past linguistic, cultural, and local differences and interpretations of the ISO language used which conflated the standard's meaning. The images used to illustrate ISO 31000 went through one iteration in the draft, 2017(e), (Fig. 2) and then was finalized in 2018 (Fig. 6).

The most noticeable change was using a circular model rather than square. For each of the ISO 31000 components (principles, framework, and process), a core was created that is central in each distinct component. The iterative and holistic nature throughout all the risk management concepts is emphasized with the use of arrows: moving from the Principles to inform



Risk Analysis: National and International Standards, Fig. 2 ISO/DIS 31000:2017 Risk Management-guidelines Draft (ISO 2017)

both the Framework and Process; arrows pointing back and forth between the Framework and Process; and arrows moving in clockwise and counterclockwise directions within the Process component.

Principles

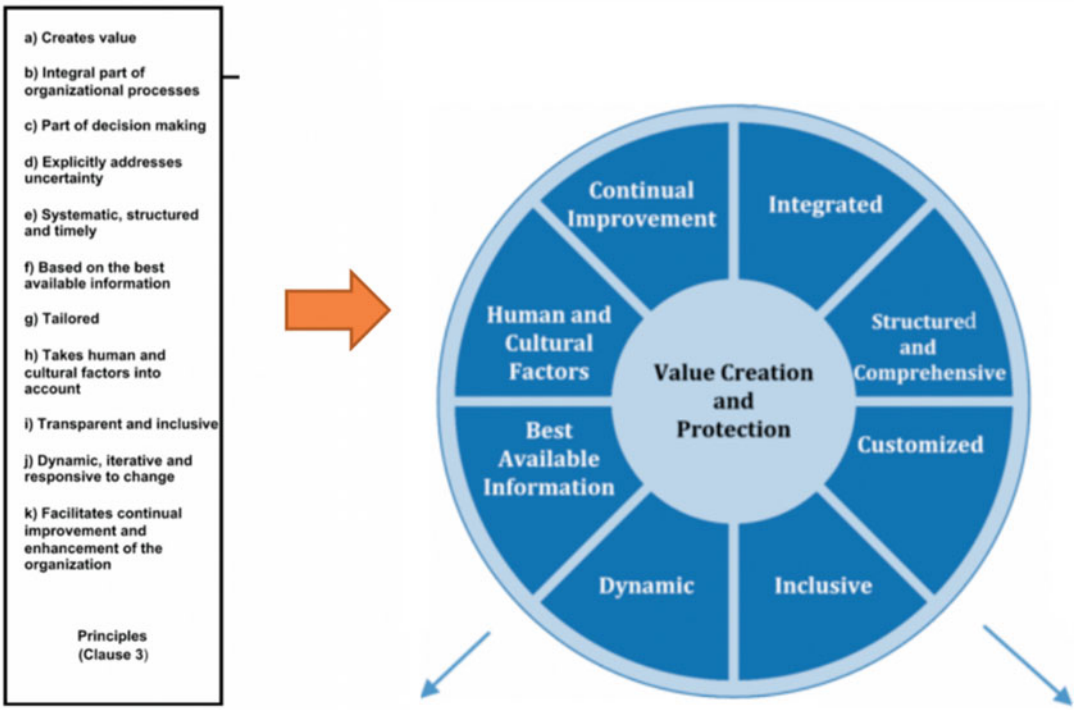
Risk management has traditionally referred to protection where risk was viewed as negative and the goal was to transfer away from risk (Gjerdrum 2018). Changing from (Clause 3) Principles in Fig. 1, the new ISO 31000: 2017(e), Fig. 2, and eventual ISO 2018, Fig. 3, includes value creation at its core, together with protection (Gjerdrum 2018). Risk is seen as uncertainty, and it can be optimized to reach organizational objectives (Gjerdrum 2018). There is an emphasis on objectives; prioritizing activities and budgets; support in taking risks and making better decisions; and driving innovation and leadership (Gjerdrum 2018).

Value creation and protection are at the core of the image and refer to the assets and objectives of the organization (Esposito 2017). Esposito (2017) explains that less downturns and negative events are the goal of value creation and protection.

Overall definitions in the Principles section were reduced from 29 to 8. Definitions which were commonly understood and seemed duplicative were removed (Gjerdrum 2018). Other terms were simplified, such as tailored being replaced with customized, for greater clarity and less confusion (Gjerdrum 2018). In summary, although the language was made clearer and more concise, the chronological and linear nature of Risk Management Principles was replaced by a looser and more iterative model.

Framework

At the core or nucleus of the Risk Management Framework component are leadership and



a) Creates value
b) Integral part of organizational processes
c) Part of decision making
d) Explicitly addresses uncertainty
e) Systematic, structured and timely
f) Based on the best available information
g) Tailored
h) Takes human and cultural factors into account
i) Transparent and inclusive
j) Dynamic, iterative and responsive to change
k) Facilitates continual improvement and enhancement of the organization
Principles (Clause 3)
Continual Improvement
Integrated
Structured and Comprehensive
Customized
Inclusive
Dynamic
Best Available Information
Human and Cultural Factors
Value Creation and Protection

Risk Analysis: National and International Standards, Fig. 3 Comparison between Principles 31000:2009 (ISO 2009) and ISO 31000: 2018 (ISO 2018)

commitment. If management is not committed to risk management, then it will not be effective.

Previously, in ISO 31000: 2009, there was only input from the Principles into the Framework, and now, with ISO 31000: 2017 (e), Fig. 2, and ISO 2018, Fig. 4, all aspects of the Risk Management Process can also be incorporated into the Framework and all aspects of the Framework can be incorporated into the Process. They are all interrelated.

"Mandate and Commitment" is now "Leadership and Commitment" because not every organization will issue a "mandate" for risk management (Gjerdrum 2018). The term mandate implies policy, whereas leadership is more realistic and flexible, making it customizable (Gjerdrum 2018). "Monitor and Review" are now "Evaluation" as there was a concerted effort to use terms tied to business objectives: Design, Implementation, Evaluation, and Improvement (Gjerdrum 2018).

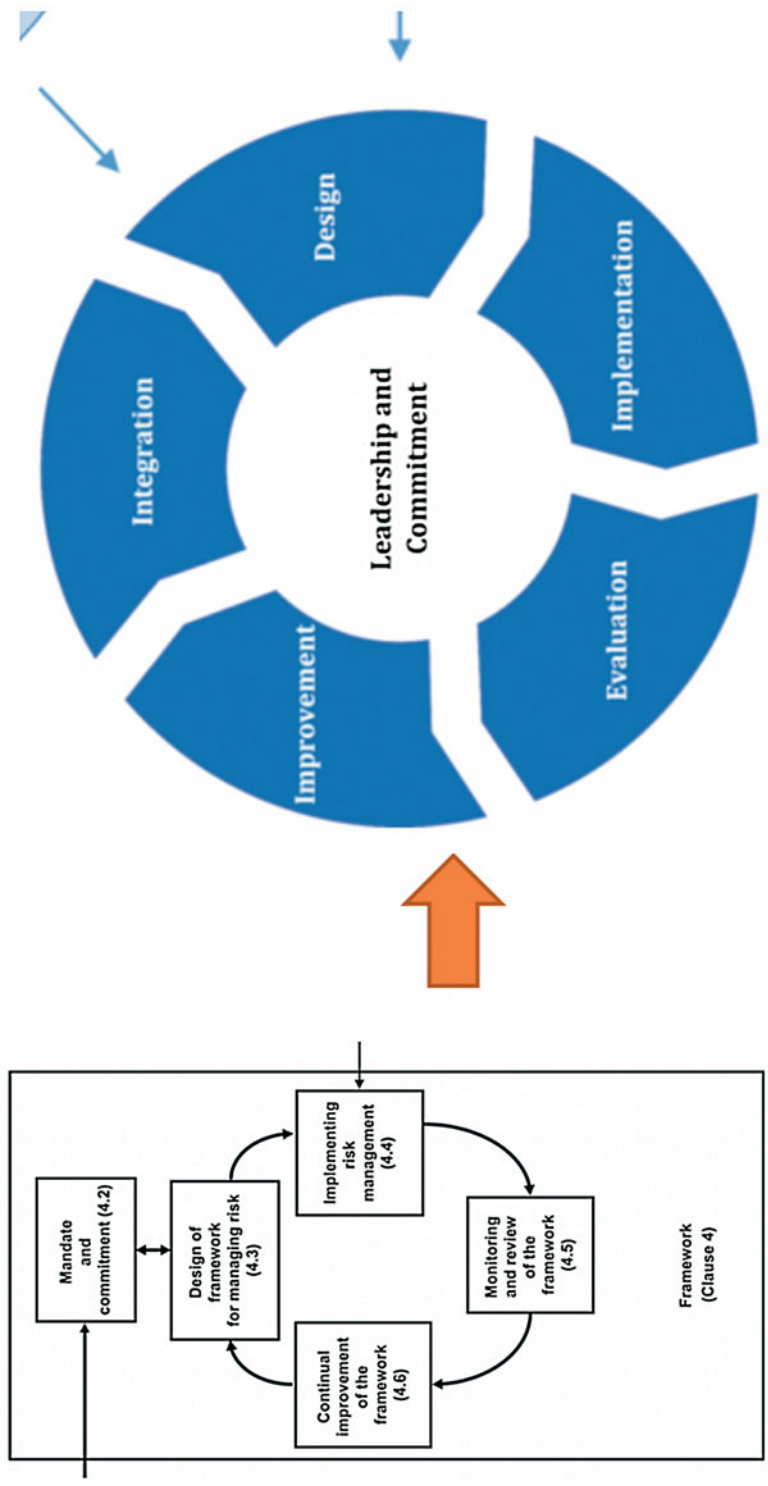
Risk Management Process

Risk may be managed well at your organization, but there may be some steps which are overlooked. The risk management process can be improved by going through the process steps according to ISO 31000. The scope, purpose, context, and criteria, in the top small light blue box of Fig. 5, need to be set before work begins on the risk management process to identify and analyze risk (Gjerdrum 2018). Everyone in the organization benefits from understanding which uncertainties are potentially most critical and may need attention. The management of risk should be incorporated at every level of the organization – from broad a strategy setting to individual decision-making.

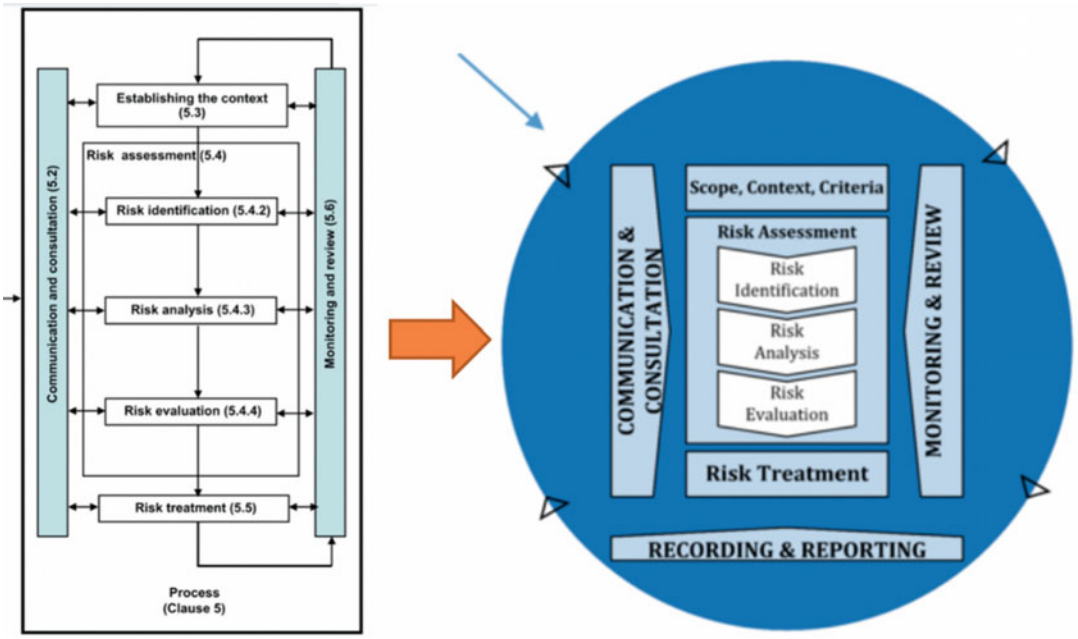
Best Practices Overview

ISO 31000:2018

Between ISO 31000: 2017 (e) and ISO 31000: 2018, minimal changes were made, and the new Risk Management Standard was to be integrated into all organizational activities, especially decision-making (Gjerdrum 2018).



Risk Analysis: National and International Standards, Fig. 4 Comparison between Framework 31000:2009 (ISO 2009) and ISO 31000:2018 (ISO 2018)



Risk Analysis: National and International Standards, Fig. 5 Comparison between Risk Management Process 31000:2009 (ISO 2009) and ISO 31000:2018 (ISO 2018)

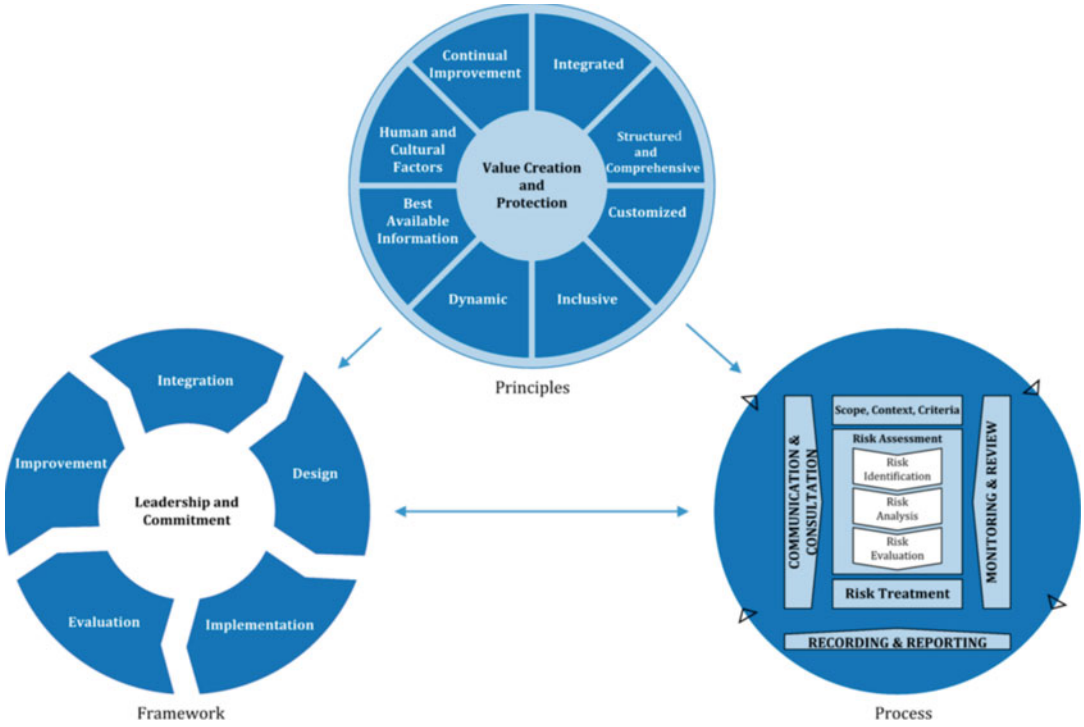
The chair of the technical committee on risk management (ISO/TC 262), Jason Brown, states that the revised version of ISO 31000, Fig. 6, focuses on integration within the organization in relation to the role of leaders and their responsibilities. Its "open system" approach lets it be effectively applied on multiple levels and in several national contexts (Brown 2017). Risk management has become an integral part of business (Stanchard 2018).

The 2018 version is much shorter than the previous 2009 standard, and there were many improvements in preciseness and language (Brühwiler 2017). The generic and "user-friendly" qualities of ISO 31000: 2018 exemplify its evolution. The principles also "inform both the framework and process" of ISO 31000, influencing "the structure and design of the framework for managing risk" (Gjerdrum 2018).

The Risk Management Framework was updated to emphasize integration throughout the organization (Gjerdrum 2018). The model used includes aspects of leadership and management that are more central to risk management (Gjerdrum 2018). Understanding the scope and the context and setting risk criteria *before* working through the risk management process is crucial (Gjerdrum 2018). Recording and reporting were also added and made more explicit (Gjerdrum 2018).

Designing an ISO 31000 Risk Management Framework calls for risk knowledge, skills, and abilities that must be customized to an organization's unique context (Hutchings 2016). Gjerdrum (2018) states that many times, the Framework is established before implementing a policy of how it is going to happen because most organizations are not policy driven nor do they have mandate or compliance concerns.

A new focus with 2018 is the shift to consider stakeholder views, perceptions, and interests as part of a risk management framework, program, and process (Gjerdrum 2018). Stakeholders are people and organizations "that can affect, be affected by, or perceive themselves to be affected by a decision or activity" (Gjerdrum 2018). Stakeholders can be internal (employees) and external (government and regulators) and need to be



Risk Analysis: National and International Standards, Fig. 6 ISO 31000:2018 (ISO 2018)

accounted for in any risk management process (Gjerdrum 2018).

The risk management process focuses on risk assessment (Gjerdrum 2018). In the risk assessment portion of the risk management process, risks are identified and defined. There is an analysis of whether those risks will happen and, if so, how serious they might be (Gjerdrum 2018). When doing risk analysis, risk is put into distinctive buckets, as illustrated in Table 1 (Esposito 2017).

Here, tolerance of risk is measured. If there is high risk, the activity is not permissible, the job must be stopped, or there may be continuous oversight and monitoring (Esposito 2017). If there is a serious or medium risk, the risk may be allowable, but one should be continuously looking for ways to improve or reduce the risk (Esposito 2017). Controls such as elimination, substitution, and barriers must be looked at, and multiple layers of protection may be implemented (Esposito 2017). If there is a low risk, the organization may choose to have exposure and use

Risk Analysis: National and International Standards, Table 1 Risk analysis – consequence/probability matrix (Esposito 2017)

Risk	Definition	Example
High	Operation not permissible	Stop the job. Continuous oversight. Defense in depth or layers of protection
Serious	High-priority remedial action	Controls such as elimination, isolation, substitution, and barriers are preferable. Defense in depth or layers of protection
Medium	Take remedial action at appropriate time	Utilize hierarchy of controls. If controls are limited to administrative or personal protective equipment (PPE), add defense in depth or layers of protection
Low	Risk acceptable, remedial action discretionary	May be able to rely on administrative and PPE controls

controls such as administrative influence or personal protective equipment (PPE) (Esposito 2017).

Ultimately, with ISO 2018, a more permeable and accessible standard for risk management has been formed which takes into account the unique characteristics of a setting or organization regardless of where it is situated in the world.

Conclusion

Today's landscape of both natural and human-made threats continually presents levels of risk to organizations. With threats becoming more complex, organizations must understand the importance of risk analysis to help address those threats. There is little doubt that organizations that do not adapt risk analysis processes and planning will be ill-equipped to address future threats and minimize disruption to operations. As articulated within this entry, comprehensive and sound risk analysis is built upon national and international standards. These standards provide guidelines ensuring that risk managers have a vetted and comprehensive framework to leverage in which conducting organizational risk analysis initiatives.

Differences in policy and procedure among national and international standards are a result of the competing, varying needs and interests of stakeholders and locales. Stakeholders may include legislative bodies, insurance companies, consumers, shareholders, management, employees, trade unions, nongovernmental organizations, industry, the public, and much more. While participation on TC 262, the technical committee which oversees ISO 31000, is "formally open to all interested parties, voluntary market actors and expert knowledge largely dominate standardization committees" (Hauert et al. 2013).

Organizations use standards to "ease transactions and to structure their internal affairs as well as the world around them" (Botzem and Dobusch 2012). However, "reconciling the international scope of standards devised within ISO with strategies geared to national or regional projects and regulations is a challenge" (Graz and Hauert 2019). There is "great diversity once you get below the principles and framework" [of ISO 31000] and the "quality of application is affected by experience and local conditions" (Brown 2017). Plainly, international standards like ISO 31000, while intended to be both macroscopic and microscopic in nature, can sometimes fall short in local and granular instances.

One of the challenges of risk management is that various sectors have very disparate understandings of risk management and even speak in dissimilar ways about it (Marinelli 2017). Most areas see risk only "from the negative standpoint and are repelled by the standard as soon as they read the risk definition" (Marinelli 2017). Managers are sometimes "unaware or are not ready to recognize risks" because risk is contrary to their ambitions and strategic goals (Brühwiler 2017). Risk perception is challenging because outcomes and deliverables are generally focused on positive results. Risk is rarely seen as positive or as opportunity to grow.

Adding practical examples of implementation of a standard may remedy any vagueness which may be perceived. Explaining positive risk and explaining how it allows for opportunities is the "only way people outside the risk management will be able to embrace the standard" (Marinelli 2017). While stakeholders may include everyone affected by the standards, ISO 31000 has come from an area of industry which can also be viewed as problematic because local elements can be overlooked in standardization (Marinelli 2017). From financial and insurance industries to government to public and private organization to universities, to urban planning sectors, ISO 31000 is viewed as accommodating and not obstructive. The ISO 31000 Standard brings more harmony than discord to the global order of risk management. The evolution and flexibility of the Standard allows it to be adapted in an array of situations, organizations, and geographic settings.

Definition

Robots are machines with computer software that are designed to automatically perform a variety of noncomplex and/or complex tasks.

Introduction

Robots are machines with computer software that are designed to automatically perform a variety of noncomplex and/or complex tasks. Some robots look like machines (e.g., SoftBank Robotics' Pepper and Knightscope's Rosie), while others are anthropomorphic (e.g., Hanson Robotics' Sophia)

(Fouraker 2018; Son 2018). Robots are deployed in public and private sectors around the world to cut costs associated with human labor and to enhance the efficiency of operations. Robots are predominately built to enable their real-time and remote access for efficiency purposes. The real-time and remote access of robots adversely impacts the security of these objects and the privacy of data aggregated, analyzed, and shared by these objects.

Robots in Critical Infrastructure Sectors

Robots have been deployed in many critical infrastructure sectors for a variety of reasons. In the commercial sector, robots are used in certain subsectors, such as retail and lodging. For example, robots have been used in the hospitality industry (e.g., hotels). Japan is famous for its hotels with robots, which not only check-in guests, clean rooms, store luggage, and bring luggage and other items to guests' rooms, but are also located within the guests' rooms to provide them with services (Choi et al. 2020; Malaea 2019). During the 2020 coronavirus pandemic, robots were used in Japan to greet coronavirus patients placed within hotels (Reuters 2020). Some US hotels also use robots to deliver items to guests' rooms, among other activities (Martin 2016). In addition, robots have been used in the: healthcare sector to conduct remote robotic assisted surgeries; manufacturing of goods, such as cars and digital technology; financial sector for customer service (e.g., Pepper has been deployed in HSBC banks branches); transportation sector, particularly the airports to provide travelers with flight and airport information and to clean airports; and defense sector, where robots deliver goods and services, and even medical care in battlefields (Son 2018; Fouraker 2018; Babe 2017; Holmes 2020; D'Monte 2015; Creswell et al. 2018; Beiser 2018; Sykes 2018).

Moreover, robots are used for security and emergency management purposes. For instance, Talon and PackBot robots are used in border security to investigate tunnels found at the US border, which are used to illegally smuggle drugs, weapons, and people into the country (McNeill and Machi 2009). These robots conduct reconnaissance and can relay information about what they find back to the agency that is using them. Furthermore, robots are used in natural and human-made disaster response because they can traverse hazardous terrains and provide relief and/or monitor locations where it is unsafe for humans to be (e.g., locations with extreme radiation levels that would cause harm to human beings).

Security Concerns

Many robots were not built with cybersecurity and/or security in mind. Because of this, robots are susceptible to cybersecurity threats because they can be remotely accessed for maintenance and operation. A case in point are the vulnerabilities identified in the in-room robots of Japan's HIS Group hotel chain. Specifically, the vulnerabilities enabled remote access to the in-room robots and enabled perpetrators to control the camera and microphone in order to see and listen to the guests in the rooms (Parrish 2017). Robots interact with their immediate environments and collect and process contextual information to operate within these environments. These operations result in the vast collection, processing, and ultimately sharing of contextual information. The privacy implications of the collection of these vast quantities of data needs to be considered.

Robots are further vulnerable to supply chain risks, from the design of the product, to its development, to the creation of the final product. One such risk involves vendors that provide critical components for robots (e.g., microcontroller). For instance, outsourcing these components to a company that is located in a foreign country can provide the foreign country with the ability to introduce a hardware vulnerability that could be exploited by the country at a later date. Software or hardware with malware may also be used to create the robots and/or the software applications used with robots may be vulnerable to cyber-attacks. Vulnerabilities in third party applications required for the monitoring and remote

operation of robots may also be present. Interconnections of robots to other digital technologies, and even other robots, create new vulnerabilities. These vulnerabilities include the interception of data being transferred, the surreptitious monitoring of data, and the gaining of unauthorized access to the administrative capabilities of the robots. The vulnerabilities enable perpetrators to surveil the environment within which they operate and/or control the functions of the robots in order to modify, disable, or otherwise interfere with the normal functioning and operations of the robots.

Finally, robots may not operate as intended and/or may malfunction, resulting in damage to property, injury, serious harm, and/or death. There have been several instances of maloperations and malfunctioning of robots. In Alabama, a woman in a factory, Ajin USA plant, was crushed to death by a car-robot, when it restarted as she was trying to determine why it malfunctioned (Silverman 2017). In California, a mall security robot knocked a toddler down and ran him over in the Stanford Shopping Center (McFarland 2016). The toddler sustained minimal injury to the leg. Surgical robots have also malfunctioned causing minor and major injuries, even death (BBC 2015).

Conclusion

The security concerns regarding robots involve both the data processed, stored, communicated, and shared by the robot, and the unauthorized access and use of the robot. Data obtained, processed, and transmitted by the robots should be secured, encrypted, or otherwise obfuscated to protect the confidentiality and integrity of data. Robot security can be implemented at the design level by creating secure firmware and software. Any default usernames and passwords, wherever present, should be changed by the users or operators of the robots. Because unauthorized access to robots can destroy, disrupt, and degrade robot capabilities and operations, robots should be developed in a manner that enables them to withstand cyberattacks.

SCADA

Marie-Helen Maras
Department of Security, Fire, and Emergency Management, John Jay College of Criminal Justice, City University of New York, New York, NY, USA

Keywords
Industrial control system · Critical infrastructure · SCADA

Definition

A supervisory control and data acquisition system (or SCADA) that monitors, controls, and otherwise supports critical infrastructure.

Introduction

An industrial control system is a general term used to describe "command and control networks and systems that are designed to support industrial processes" of critical infrastructure (ENISA n.d.). Critical infrastructure includes assets, systems, and facilities that are considered so vital to the United States that the incapacity or destruction of them would have a debilitating impact on society (Maras 2014, 2016). The focus of this entry is on one type of industrial control system, a supervisory control and data acquisition (or SCADA) system.

SCADA: In Brief

SCADA systems monitor, control, and otherwise support critical infrastructure. These systems "are highly distributed systems [and are used for remote monitoring and control over] geographically dispersed assets. They are used in distribution systems such as water distribution and wastewater collection systems, oil and gas pipelines, electrical power grids, and railway transportation systems" (Bobat et al. 2015, p. 2108; Stouffer et al. 2015, p. 2), among other areas. For example, in water distribution and wastewater collection systems and gas pipelines, they are used to monitor flow of water and pressure of gas in pipelines (Stouffer et al. 2015).

Vulnerabilities

SCADA systems are vulnerable to both physical threats (e.g., natural and human-made disasters, such as floods, fires, and even terrorism) and cybersecurity threats (e.g., unauthorized access or the exceeding of authorized access to systems). For instance, in 2000, Vitek Boden, a contractor for a company that installed the SCADA system for a sewage treatment facility in Australia, remotely hacked into the system and released

https://doi.org/10.1007/978-3-319-70488-3

sewage near the facility (Maras 2014; Sayfayn and Madnick 2017).

There are special considerations for securing SCADA systems due to their design and functions (Stouffer et al. 2015). Because of their design and functions, SCADA systems are vulnerable to both remote unauthorized access through the channels used for their maintenance and the implantation of faulty data (which comprises the integrity of the data). In view of that, SCADA systems require strict access control features to prevent their unauthorized access and use.

There are several obstacles to securing SCADA. Given that some SCADA systems rely on proprietary operating systems, upgrades are not straightforward, and any changes to their operating systems need to be made by the vendors (Stouffer et al. 2015). In addition, "third-party security solutions [and support] are [often] not allowed [on such systems'] due to... vendor license and service agreements" (Stouffer et al. 2015, pp. 2–15). This is particularly problematic as vendor support may not be available when the support is needed, and service support may be lost if third-party applications are used and/or security solutions and/or support is obtained without prior agreement of the contracted vendor (Stouffer et al. 2015).

SCADA software and hardware applications are also more difficult to upgrade, and some systems may not have important security features, such as encryption (Stouffer et al. 2015). Unlike traditional information technology systems, software updates for SCADA systems, including security patches, are not applied in a timely manner (Stouffer et al. 2015). In fact, these updates are infrequent because vendors have to test these updates before implementing them – because of this, updates must be planned and scheduled well in advance (days and maybe even weeks in advance) (Stouffer et al. 2015). What is more, the components for these systems are also generally not easy to access and require a significant amount of effort to access them.

These challenges have led to "a significant transformation [of some industrial control systems] from proprietary, isolated systems to open architectures and standard technologies highly interconnected with other corporate networks and the Internet" (ENISA n.d., para 2). This transformation, however, has brought about new vulnerabilities to cyberattacks (for more information about vulnerabilities to industrial control systems and critical infrastructure, see the *industrial control system* and *critical infrastructure* submissions in this encyclopedia, as well as the individual submissions for each of the 16 US critical infrastructure sectors: chemical; commercial; communications; critical manufacturing; dams; defense industrial base; emergency services; energy; financial services; food and agriculture; government facilities; healthcare and public health; information technology; nuclear reactors, materials, and waste; transportation systems; and water and wastewater systems).

Conclusion

A SCADA system is a type of industrial control system. The protection efforts for SCADA systems must take the abovementioned special considerations and security obstacles into account to ensure that adequate protection is provided against both physical and cybersecurity threats.

Security: Concepts and Definitions

Security · Securitization · Public and private security

Definition

The measures taken to prevent, or respond to, criminal behavior.

Introduction

The concept of security literally refers to "a state of being free from danger or threat" (Oxford Dictionary). This is a very broad definition, and the word security is therefore used in different ways in different contexts. It may refer to a state of being free from many kinds of dangers and threats (e.g., war, unemployment, illness, or accidents). Some commentators have identified the fact that when security is used in this broad way, what is actually meant is *in*security (see, e.g., Schuilenburg and Van Steden 2014). In this context, it is important to point out the difference between "security from" (shielding from harm) and "security to" (enabling people to pursue their goals) (Crawford and Hutchinson 2016).

Security as a Contested Concept

Security as a concept is highly contested: there seems to be little agreement over its meaning (Crawford and Hutchinson 2016). Contributing to this situation is the existence of the closely connected concept of "safety." Safety also refers to a situation of being free from danger and risk but is more closely connected to physical conditions such as being free from injury. In practice, the difference between security and safety is commonly expressed as "safety" being about a situation of being free from physical harm or risk and "security" as being comprised of the measures taken to prevent, or respond to, criminal behavior. This is the definition used here. Security has, in this sense, moved away from being a state of being toward being a commodity.

Public Versus Private Security

Security provision can be organized by states (public security) or others (private security).

Sociologist Max Weber (1946) has famously stated that the monopoly over legitimate use of force is the essential tool of governance of states. In this view, security "is" public security. Taking a historical point of view, however, scholars such as Garland (2001) tell us that the monopoly of the state on security matters is an anomaly. In most of history, security provision has been a shared task of public and private actors, and the growing involvement of private actors in recent years indicates a move back toward that "normal" situation. One force driving the development of private security is the growth of mass private property in society (Shearing and Stenning 1981). (Semi-)public spaces (such as shopping malls and amusement parks) are often located on private property. This development fuels the growth of the domain of private security as well, simultaneously diminishing the domain of public police (Jones and Newburn 1993). In this way, security provision gets fragmented and divided among public and private actors.

Private security provision takes many different shapes. It can be about the provision of physical security (cash-in-transit, guarding of personnel or specific places such as an embassy, event, airport, the railway, maritime security, or a mall), of corporate and investigative services (such as employee theft or intelligence), of technical security services (such as alarm systems and camera surveillance and cybersecurity), or even of (para) military services. In addition to state-provided or private security, public/private partnerships and hybrid public/private entities have emerged (Jones and Newburn 2006).

Public Good or Private Commodity

As noted above, security is not exclusively provided by either the state or private parties. This fact has propelled an interesting debate that revolves around the question of the nature of security (Crawford and Hutchinson 2016). For some, security is a commodity which can be commercially traded and sold. Nodal perspectives on security tend to take this point of view, stating that we should view security as a commodity which is traded in the market, in which a multitude of (public and private) providers deliver security services. Security nodes provide security consumers with a choice, which is seen as a social good. The utilization of localized knowledge is regarded to make these security nodes more effective than state-provided security. The state is part of this complex of security nodes, but not prioritized over other security providers (Shearing 1992).

Others, also acknowledging the pluralistic nature of security, continue to see an essential role for the state. This is a result of their view that security is a public good, the provision of which cannot be left to the market (alone). The perspective of anchored pluralism concedes the fragmentation and pluralism of the market for security, while simultaneously prioritizing the state as a venue for security services over other actors (Loader and Walker 2006). Security is seen as a "thick" public good which consists of three dimensions. First, security is instrumental in the sense that it is a prerequisite for the enjoyment of – most notably – freedom. Second, security has a social dimension, in as far as the security of individuals is reliant in part on the security of others. And thirdly, security has a constitutive dimension: security helps constitute social cohesion and solidarity in a society. In the anchored pluralist view, security is not just about security (and safety) but also about justice – and the state is seen as the essential venue for that.

Governmentality and Securitization

The emphasis on security in contemporary society has been identified as "a culture of control" (Garland 2001) and as a securitization of society (e.g., Rose 1999; Schuilenburg 2015). In this context, the ideas of Michel Foucault are highly important. In his work about "governmentality", Foucault (1978) explains that security is used as a means to govern the population of a society. In this process, the state relies on other actors as well to be part of its "governance through

security agenda". Both the processes of securitization and the formation of a culture of control build on Foucault's ideas, referring to the situation in which security has become a dominant governing tool throughout society. Security has come to contain much more than reactions to crime, now also including undesirable behavior and disorder. It can even be said that security is the leading concept in society, guiding the way we think about a large diversity of subjects (Crawford and Hutchinson 2016). The scope of surveillance in contemporary society is unprecedented (Schuilenburg 2015).

Conclusion

Security is a contested concept. This is significant in the context of its importance for contemporary society. "Security" is omnipresent: as a mechanism to govern society, as an employer for many citizens, and as a substantial and ever-growing market for security consumers and providers. Whether security should be seen as a commodity or a public good, it impacts the everyday life of most citizens in modern society.

Outsourcing · Nonorganizational security · Physical security · Private security firms

Definition

Contract security refers to an organization that vends their security services for an organization that needs to protect their assets using physical security (manpower) with a degree of technology, if applicable.

Introduction

Most of the USA's critical infrastructure systems are privately owned and are protected using private security officers (Strom et al. 2010). Large and small businesses, residential housing, educational facilities, governmental agencies, and other segments of business may decide for a variety of reasons to outsource security by hiring a company or guards to protect employees, property, and customers. In fact, most chief security officers when surveyed by ASIS International (see Nemeth 2018, p. 129) indicated that they used contract security (63%) over in-house/proprietary (6%) or hybrid (31%) security. At the beginning of 2018, the total worldwide revenue generated by contract security firms exceeded 26 billion dollars (Perry 2018).

The company's or end users' decision to seek a contractual firm to provide security is often based upon the desired needs of an organization (Nixon and Kerr 2008). To make this determination, the company CEO should consider the following four questions:

- Does the decision maker have any in-house experience in the industry?
- Is that person someone in a leadership role who has knowledge of security applications?
- Is that person someone who can dedicate his/her time to oversee security?
- Does the firm have the resources (either monitory or staff) to self-employ?

These are just some of the questions which must be considered, and when answered in the negative, means that the firm should seek a contractual firm to provide security services rather than performing security for itself (i.e., proprietary security). This chapter will provide information regarding the benefits of contract security, as well as what companies should consider when deciding which contract security firm is best for their needs.

Benefits of Contract Security

The primary benefit of contract security is reduction in costs associated with recruitment, screening, and training of security personnel and in administration and operation overhead (Fischer et al. 2013; McCrie 2016). Secondary benefits include obtaining security that meets industry standards for expertise, distributing risk and legal liability toward vendor, and allowing end user risk managers to perform internal investigations and focus on information security (Fischer et al. 2013; McCrie 2016; Nixon and Kerr 2008).

Cost Benefits

One of the most overlooked benefits relative to cost is not that a contractual security service is in itself necessarily cheap, but rather the establishment of an hourly billing rate means that the company or end user can establish and manage its security budget for the year. Listed below are items which are packaged into the hourly cost of a security officer and, unless renegotiated during the term of the contact, remains fixed. Additionally, the end user hiring a contract

security organization or vendor can lower associated security costs because it will not be responsible for security equipment (e.g., patrol cars, uniforms, surveillance TVs) or personnel-related costs (Fischer et al. 2013).

Security Officer Payroll. In the industry, there is some controversy regarding whether contract security officers make less than those working for a proprietary organization. However, what is undeniable is within the agreed-upon billing rate, a variety of other costs are absorbed (Brownyard 2015). Inherent in any company's payroll are certain tax and associated burdens: items such as employer-mandated taxes, which include a portion of federal payroll tax (#941) and federal unemployment insurance (#940); applicable State Unemployment Insurance (SUI); as well as state mandated Worker's Comprehension Insurance and General Liability Insurance (see Averkamp 2019 for an explanation). The cost of employment benefits, including vacation time and mandated sick leave days (this mandate continues to pick up momentum as large cities such as New York and Los Angeles have implemented this employment regulation). Probably the greatest advantage to companies in terms of contracting security is unforeseen overtime. If a security officer is required to work past his/her regular hour limit and receives overtime, it is not the responsibility of the end user to compensate the security organization. The exception would be when the company requires overtime as a stipulation in the contract terms and agrees to pay for such service.

Training. Adequate training has to be an important aspect of any comprehensive security plan (Hertig and Davies 2011). The combination of experience and a thorough training program designed to improve the security officer's skills and knowledge are essential to a successful model. Some contractors have instructional training packages they offer to employees, increasing their own marketability (Hertig and Davies 2011). In most states, however, preemployment training is the responsibility of the candidate and not the cost burden of either the security firm or the end user (Nemeth 2018). Often a candidate will not qualify for employment without satisfying particular state-mandated preemployment training (Nemeth 2018). The exception for training cost to be shifted to the contractual firm is when specific training topics are a requirement of the end user. Items such as the use of access control technology, IT education, limits of and power of authority, to name a few, will most often become a cost to the contractual organization. Additionally, if the end user company at some point during the contract period seeks supplemental training, such as deportment, communication, or ethics and conduct, then this cost is often absorbed as well. Even state mandated "in-service" training can become an expense to the contractual organization (Nemeth 2018).

Administration and organization: Establishing an "in-house" (proprietary) security department requires the development, administration, and organization of a recruitment team, training programs, payroll staff, and the hiring of supervisory staff to include management (Nixon and Kerr 2008). There is little doubt that the administrative burden is significantly reduced when engaging with a contractual firm. All aspects of the hiring process are the responsibility of the vendor (Brownyard 2015). Items such as initial candidate screening, the interview process, reference checking, background review, state compliance review (when applicable), and preemployment drug screening shall all be tasks performed by the security company as part of its contractual obligation (Brownyard 2015). Along with the initial hiring phase, the vendor shall also be responsible to increase or replace the number of personal as needed or reduce the number of security officers for any reason (Brownyard 2015).

Supervisory personnel must also be part of the hiring process as direct supervision and oversight of all officers is the responsibility of the vendor. Proper management of site-specific duties, file maintenance, and incident report review are all functions that is the responsibility of the security firm (Brownyard 2015). Once staffing has been fulfilled and security training satisfied (see aforementioned training section), there is a financial obligation on the part of the contractual firm to

fund payroll on a weekly or biweekly basis. One of the quickest ways to create disgruntled, poorly performing, and overall dissatisfied security personnel in the contractual firm is to have systemic payroll problems, specifically, delays in the issuance of payroll, inaccurate payroll, or lack of funding resulting in payroll obligations to be unsatisfied. Any of these problems will undoubtedly lead to high turnover and cause a degree of confused and unsettled behaviors regarding proper staffing for the client.

File maintenance is another significant issue relevant to both contractual and proprietary organizations. Many states have mandates requiring that various documents be made available for review, in either the client file or employee jacket, for inspection by an authorized agent of a particular state. State-approved employment applications, copies of registration cards, proof of training, client contracts, and proof of insurance are just a few items many states require companies to have on hand. Contractual firms have a much better understanding of the applicable state rules and regulations as they deal with these issues more often than do any in-house security organizations.

Operational Benefits

Often considered the most significant value-added component of utilizing a contractual firm is its obligation to provide continuous service, even during the most extreme circumstances. The "back room" or dispatch center for a contractual firm is the heart beat of the organization as it must provide the client with security coverage even when regularly assigned officers call out sick, have scheduled time off, or simply do not show up for work. Fulfilling this contractual obligation proves costly as most times officers will be entitled to overtime pay while transferring between job sites (after completing his/her assignment). Once again, with very few exceptions, the contractual firm will not be entitled to charge the user company anything beyond the agreed-upon hourly rate, even though an added payroll burden was necessary to satisfy the contractual obligation of the vendor (Brownyard 2015).

The deployment of additional manpower during emergency situations would also be the responsibility of a dispatch center. As the cadre of officers in a mature organization would be greater than in a proprietary firm, the advantage of engaging a contractual firm is clear. The oversite and coordination of supervisory personnel is also the function of the operational team. The ability and requirement of supervisory personnel to visit a client venue is paramount to the success, satisfaction, and retention of the client. Often the function of the supervisor, as well as the on-site security officer, is written into the client contract, and the oversight of these duties is the responsibility of the contractual firm. Once again, this added value is of no additional charge to the client and embedded into the hourly billing rate.

Impartiality. In many cases, the contractual security officer can more readily, effectively, and without consequence enforce the rules and regulations provided by the user firm than a proprietary officer can (Hertig and Davies 2011). The general reasoning is that the contractual officer is employed by and paid by a firm other than the one to which he/she is assigned. The fact that the security officer has little, if any loyalty, to the user firm is of great advantage when enforcement of particular rules and regulations is required. Assignment rotation also discourages familiarity with in-house personnel and can be a useful tool against allowing unauthorized access of certain employees or the occasional breach of policies and procedures. If properly managed, this situation produces more consistency in the performance of job site duties.

Conclusion: Selecting a Security Vendor

There are few things in the business world that could replace experience. Selecting the proper security vendor for any company is of great importance and should be beyond the scope of cost alone. Items such as deliverables and positioning are two segments which must be considered and equally evaluated in the decision.

Deliverables. Deliverables refer to how the security vendor provides its service to the end user company. The items included are the type of technology based upon historical data, as well as levels of staffing based upon job site duties and requirements. Often assisting the client to define site-specific requirements and operational duties, then shaping these duties into easy-to-understand instructions is something that is enormously helpful to the user agency. Other areas such as reporting procedures, communication, planning, and performance audits all fall under the category of deliverables and should not be overlooked during the selection process. In particular, as end user companies do not have direct control over security matters, including disciplining officers who do not perform their duties, it is essential that they are able to communicate such issues and concerns to the contract firm.

Positioning. Positioning refers to the security firm's experience and service record. When deciding which contract firm is best for your company, you should ask the following questions:

- How experienced is the security firm in your segment of industry?
- Does the security firm currently provide service in this segment to other companies?
- Historically, is this a segment in which the security firm is considered an expert?

Many initial concerns are often eliminated simply due to the fact that the security firm is well-positioned in this segment and has the ability to anticipate certain problems. Assigning the best candidate with the most experience based upon recruitment and training to your location is easier due to the level of expertise the firm has in providing security in your field. Management and consulting are of great value as experienced leadership employees with the security firm help provide information as to which services should be promoted in favor of others. This is often an indication for where the segment is moving to and as to what to achieve in the future. Finally, the ability of the user firm to solicit advice and consultation from a firm with a degree of experience in a particular segment should provide a level of comfort knowing that suggestions and/or direction is being offered through experience and not based upon a best guess.

Definition

Hybrid security refers to the use of both contracted and proprietary security services to protect a company's assets.

Introduction

Businesses that have a need for security often inquire about security services that would be best suited to their organization (Nixon and Kerr 2008). Traditionally, businesses will choose from establishing a proprietary organization within their company (i.e., hire their own staff; McCrie 2016; Perry 2018; also see ▶ "Security: Proprietary" in this volume) or use a contract company (i.e., hire a security agency to provide staff; Fischer et al. 2013; McCrie 2016; also see ▶ "Security: Contract" in this volume) to satisfy their needs. As there are advantages and disadvantages to both proprietary and contract security services, the hybrid security model provides an excellent example of how the two types of services can be combined to give the company the best coverage (Nemeth 2018). When deciding between proprietary and contractual services, the company must consider cost, quality, and management needed to carry out both short-term and long-term security operations (Fischer et al. 2013; McCrie 2016). However, by employing a hybrid model of security, the company can maximize benefits and minimize difficulties typically provided by each. This chapter provides a review of each type of security model and describes the best use of the hybrid model.

Contractual Versus Proprietary Security

Contractual security service refers to security services that have been outsourced to a private or public entity in need of security services (Brownyard 2015). The security officers are recruited, screened, hired, properly trained, supervised, and managed by the contracted company (Nixon and Kerr 2008). Contractual security services are able to manage absences of personnel in an organized manner as they are flexible in terms of replacements and coverage, thereby providing a consistent presence at all posts with trained officers (Hertig and Davies 2011). When using contractual security service, the organization transfers their risk or liability to the contracted company meaning that any losses that are sustained during work are compensated by the contracted company through its insurance policy.

Proprietary security operations are those that are "in-house" or controlled entirely by the company, and these employees are loyal to the company (Sennewald 2011; Zalud 2007). Recruiting employees and providing administrative support are the tasks of the in-house organization, making operations financial costly, both in terms of hiring, payroll processes, and tax information needed for each security employee and in higher additional administrative and operational expenses (Nemeth 2018).

Whether using proprietary or contractual security services, the organization is responsible for providing all tools necessary in order to run a successful security operation, including cameras, monitoring systems, and other equipment. By establishing an internal security operation within the organization, the organizations directors can regulate policies and procedures for security staff (Zalud 2007). This allows them to maintain control over the policies and their enforcement (Nemeth 2018). The directors of the organization

know the location and facility better than most other individuals, allowing them to tailor their security needs (Reilly 2013; Zalud 2007). Outside agencies, in contrast, have the level of expertise needed to conduct security operations (Hertig and Davies 2011). By maintaining internal personnel, the organization can effectively control how their security staffs conduct their operations on day-to-day basis without any interference. The organization can also set its own requirements for experience, training, and other qualifications for its security personnel (Sennewald 2011; Zalud 2007). Contracted guards are subject to certain standards and requirements in order to work, whereas proprietary services can have a hard time determining what quality is or what the standard should be.

Conclusion: Benefits of Hybrid Security

Some of the complexities experienced between traditional security services can be related back to matters in management, cost, training, quality, administration, staffing, and expertise (Nemeth 2018). Most often businesses have only considered contract and proprietary security services as their two choices (McCrie 2016). However, the hybrid security model has gained momentum to user organizations as a flexible model for protecting assets. A hybrid security model can be an ideal service for any type of business as it blends both proprietary and contract security services (Nemeth 2018). Having a hybrid security model will allow a business to maintain an "in-house" management structure; a CSO or director of security, middle managers, and supervisors are generally all employed by the proprietary firm, allowing for complete oversight of all policies and procedures. Security officers are the responsibility of the contractual firm and report directly to the in-house management staff (Reilly 2013). One of the more significant values of this model to the user firm is that all human resource, administrative, and payroll issues stay with the contractual firm and they assume the burdens associated with these tasks (Sennewald 2011). Additionally, all operational issues are directly addressed in-house as management has the ability to maneuver personal at will without the permission of the contractual firm (Nemeth 2018).

Cost can be a consideration in the hybrid model as the proprietary firm employs security leadership to include midlevel managers (Sennewald 2011). Many firms in today's market are willing to assume the expense as a trade-off to complete oversight of their security operation (Nemeth 2018). Finally, it is of great importance should a firm elect to engage this model that the proprietary organization has a significant level of comfort with their contractual partners, both in terms of their ability to satisfy all of the obligations mentioned and the degree of expertise and guidance they bring to the user organization (Zalud 2007).

Definition

Private security refers to the nongovernmental practice of protecting people, property, and information, conducting investigation, and safeguarding an organization's assets.

Introduction

Private security plays a role in protecting assets in both the public and private sectors. It means something different to the private sector, public sector, and public itself. Private security refers mainly to the use of interior and exterior measures to protect personnel and physical assets, such as access control doors, lighting in parking lots, or alarm systems. Others think of the people who safeguard assets and conduct investigations, specifically security officers, armored car drivers, or private investigators (see ▶ Private Detectives in this encyclopedia). Still, some others are concerned with cybersecurity, that is, protecting computer data, information systems, or data on the Internet.

Private security is a very large and vast field, comprised of the protection of lives and property in diverse ways, shapes, and forms. First, private security is a **nongovernmental** practice, indicating that protective services are produced by private individuals or private organizations. The origin of service products comes from private nature. In some cases, government agencies contract out part of their services with security companies, but still, the core security services and products are produced and provided by private hands. Second, services and products offered by private security are **fee-based** in case of contracted out practice. Any individual or governmental entity who needs security services pays with funds, which are either private money or public funds, to security professionals or companies. For the proprietary security arrangement, all operational cost comes from an individual or private corporate, not from public funds (see ▶ Security: Proprietary in this encyclopedia). Third, protective security services by private security are **contract-based** in case of contracted out arrangements (see ▶ Security: Contract in this encyclopedia). Unlike public police security services, where our society demands public fund-based, available 24/7, and permanent operations, security services are typically offered according to fixed temporary terms. Once it expires, the clientele can renew, terminate, or add/subtract the nature of the contract. Fourth, private security has **service-based** multifaceted aspects in its service and product.

There are other ways in which private security differs from public security. Public police are typically organized according to different governmental levels (e.g., municipality, county, state, federal, special districts, etc.) and primarily restricted to its own geographical jurisdictions. Private security, on the other hand, is based on a particular service the client is willing to purchase, which can be offered from other regions of the

USA or even from/to other countries. The client can even purchase private security services from multiple providers domestically and internationally. In this way, one security company is able to offer a variety of protective services and products (Cunningham et al. 1990; Fischer et al. 2019; Kakalik and Wildhorn 1971; Van Meter 1976).

In short, private security produces and provides protective services for life and property against hazards, including "natural" and "human-made" hazards. Examples of the natural hazards are fire, tornado, flood, earthquake, hurricane, blizzard, and other acts of nature which may result in disruptions or damage to the enterprise or organization, such as to cause building collapse, equipment failure, accidents, safety hazards, and other events that interrupt normal business processes. Examples of "human-made" hazards are crimes against the person (e.g., robbery, sexual crimes, etc.), crimes against property (theft, pilferage, fraud, embezzlement, etc.), as well as other problems, such as terrorism, espionage, sabotage, civil disturbances, bomb threats, workplace violence, cyber/Internet attacks. This entry discusses the historical development of private security, private security industry, issues regarding the roles of private security, and the future of private security.

History of Private Security

Private security has a long and sordid history. Much of the history of contemporary private security is intertwined with the history of policing. Both follow the shift and reform of legal foundations, taking the primary responsibility for protection and prevention of criminal activities from the private individual to the government. The history of private security germinates from a recurring inability of government sectors (Smith et al. 2017) and from a continual new challenge and threat to provide the level of security required by individuals and organizations.

The need for security can be traced back to the ancient world. Humans have always felt and practiced the need for security for both themselves and their possessions. Security practices and devices have been in existence for hundreds of years, dating back to 1500 BC. Two major security practices were dominated in the ancient world. First, the use of guards became popular at an early point in history, protecting persons and assets. Among the earliest examples of personal security professionals were those created in the thirteenth century BC when Egyptian Pharaoh Ramses II hired Nubians, Libyans, Syrians, and others to complement Egypt's military and native security forces. This practice continued in ancient Rome, where wealthy citizens often hired security professionals to protect their families and property. Augustus Caesar created three forces: the Praetorian Guard (as a form of bodyguard police), the Urban Cohorts (as a form of armed police, composed of soldiers with police and military duties), and the Vigiles (as a large body of police-fire fighters). This may well represent one of the first formal security forces in history (Collings et al. 2015; McCrie 2004, 2014; Smith et al. 2017).

Second, another common practice of the ancient world for protection and safety was to utilize physical security measures. For example, walls and barriers protected people and property by surrounding many cities in Europe and Asia, such as Rome, Troy, Constantinople, and the Great Wall of China. Ancient cities and palaces were surrounded by walls of great thickness and height. One such example was the Mycenaean fortresses with four zones of protection (layered defense lines) – the first line of defense with the use of water, the second line of defense with the outermost wall, the third line of defense with the wall surrounding the sacred precinct and palace, and the fourth line of defense (the final defense) with the wall of the building used as quarters for the royalty and their valuable possessions (Collings et al. 2015). This concept of sequential layers of defense lines has existed and practiced throughout all human civilizations and still applies in the twenty-first-century security operations management. Many of the developments and practices of the past are seen in today's security operations with the same goals: to keep others from accessing private property while providing individual and organizational security and protection. What has been changed is not the

fundamental principle of physical security but the asset to be protected and the technology to be implemented.

During the Middle Ages (from the fifth to the fifteenth century), security involved wealthy citizens building moats for protection of their property from potential intruders. While new policing reforms and practices had been implemented (such as tithings, shire reeve, constables, watch, ward, etc.), private police force emerged gradually to respond to new challenges. For example, by the mid-1600s, **thieftakers** acted as a private police force to capture and punish criminals. They were paid by the king for the conviction of criminals and rewarded for their efforts with the bounty of weapons, money, and property seized from the criminals they caught. They did not have any official status. By the mid-1700s in England, the **Bow Street Runners**, created and overseen by Henry and John Fieldings, acted similar to the thieftakers. There were no clear boundaries between public policing and private security until the first modern-era urban police department was established in London, UK, by Robert Peel in 1829 (Fischer et al. 2019; McCrie 2014; Smith et al. 2017). Ever since then, public police have dominated public safety and protection roles, while private security has focused its roles of protection and safety on more private individuals and private corporate business and assets. Two distinct paths toward protection and prevention between public police and private security were paved.

In the North American context, private security has excelled during the late 1800s beginning from the Pinkerton National Detective Agency in 1850. The so-called original big three, Pinkerton in 1855, Brinks in 1859, and Burns in 1909, started their private security business by providing investigation, guarding, as well as freight and package delivery. In 1850, Wells Fargo offered a freight transportation service. Then Holmes in 1858 and ADT (American District Telegraph) in 1874 both began providing alarm installation and response services (Fischer et al. 2019).

Another noticeable development between the mid-1800s and early 1990s was railroad police. As the USA expanded westward, railroad lines in the new territories received little or no coverage of protection and safety from public police. Local outlaws robbed passengers, stole cargo, dynamited tracks, and disrupted communications. Numerous state legislatures passed railroad police acts for railroad companies to establish their own security forces with full police powers in response to demands for adequate protection of goods and passengers. By 1914, there were over 14,000 railway police in the USA. In addition, steamship lines, banks, factories, mines, and retail establishments employed more and more private security professionals (Smith et al. 2017).

World War I and II became a catalyst for private security to expand its roles and activities. The use of private security increased not only because of urbanization and industrial growth but also to protect government assets against sabotage and espionage. For example, during World War II, more than 200,000 plant watchmen were given special auxiliary military police status to protect products, supplies, equipment, and personnel. The 1960s' social unrest and 1970s' sudden increase of crime rates across the nation played a critical role in the growth of private security. By the mid-1900s, many private security companies had joined the ranks (Fischer et al. 2019; Smith et al. 2017). Today, the protection and safety of our nation and our communities is a shared responsibility between public police and private security sectors. Private security is the primary resource for individual and property protection.

Private Security Operational Types and Activities

Operational management of private security services has three types: contract security, proprietary (in-house) security, and hybrid security. **Contract security** companies offer protective services for a fee to people, agencies, and companies which do not employ their own security personnel or which need extra protection. Contract security professionals are generally not peace officers with police power. In 2013, there were nearly 10,000 such companies in the USA (Fischer et al. 2019; Smith et al. 2017). Early researchers perceived more rapid growth in contract security operations

than in in-house security type, and the trend has been toward increased use of contract security professionals, products, and services. Some advantages with contract security type include cost saving, dealing with less administrative issues (e.g., recruitment program, training program, scheduling, substituting manpower, etc.), flexible staffing (e.g., laying off, taking on additional staff, or emergency use), more nonunion security professionals (i.e., only a fraction of security officers are unionized), more impartial performance of duty, and customized security services (Fischer et al. 2019).

On the other hand, proprietary (also called as in-house security) operations provide protective services for the entity and are controlled by the company. They are also not classified as sworn peace officers. About 40% of all private security officers are in a proprietary arrangement. Most of them are employed in retail/restaurants/food services (16.7%), casinos/hospitality/arenas/entertainment (15.7%), health care/medical centers/hospitals (12.9%), and government (10.9%) (Smith et al. 2017). Several advantages of in-house security operation include higher quality of security personnel, more careful employ screening processes, lower rate of turnover, greater degree of control over security personnel, loyalty, and increased prestige by building the company's own security force (Fischer et al. 2019).

The third type of security operations is hybrid systems, combining both in-house and contract security functions (see ▶ Security: Hybrid in this encyclopedia). The final arrangement among different types varies depending on the nature, location, and size of the firm. Primarily for cost reason, the number of contract security jobs is likely to increase faster than that of in-house security jobs. BLS projects employment of security guards grows by 5% between 2014 and 2024, which is about average for all occupations (Smith et al. 2017).

Whatever actual types of security operations there may be, there are still several common security functions performed by security professionals, which can break down into four main components – physical security, fire and emergency managements, information/data protection, and enforcement of rules and policies. **Physical security** functions include building and perimeter protection, intrusion and access control, and alarm and surveillance systems. **Fire and emergency managements** are related to fire prevention and control, emergency response, crisis management, and disaster recovery planning. **Information/data protection** functions are done by protection of intellectual property/data/information systems. **Enforcement of rules and policies** is operated by regulating and applying crime- or loss-related rules and policies, implementing preventive regulations of theft and pilferage and workplace violence.

Private Security Industry and Factors for Growth

The private security industry has grown tremendously since the 1970s. It is a huge enterprise that produces security hardware and provides protection services. There are between 11,000 and 15,000 such companies (not including in-house security operations) in the USA, compared to about 18,000 public law enforcement agencies, but there are more people working in the private security sector. For example, in 2016, over 1.13 million people worked as security guards and gaming surveillance officers, while about 800,000 people worked in public police (Bureau of Labor Statistics (BLS) 2019). Major categories of services private security industry provide are security forces, patrols, consulting services, investigative services, alarm response, armored car delivery and courier services, executive protection, and event security.

There are three reasons for the increased use of private security industry. First, during the last two decades, virtually all major cities and state governments in the USA have experienced severe budgetary cutbacks. Public police agencies have gone through their share of across-the-board government funding reductions, resulting in limitations and even freezing on the hiring of additional police officers. Police departments have also curtailed services, leading to an increase in the use of private security professionals and companies to fill the gap in protective services.

Second, a business depends on a positive reputation to remain competitive. Widespread employee theft, embezzlement scandals, and substance abuse all harm a private company's public image and may cause potential customers to question the quality of its products and services. By employing in-house security professionals or contracting out, companies may implement preventative programs and handle internal criminal cases.

Third, by employing in-house security personnel or by contracting out with outside security companies, management in the private sector can direct security professionals to do precisely what is needed to prevent crime, minimize substance abuse, and discipline wayward employees. It should be noted that private security employees are typically male and white. In 2015, security guards and gaming surveillance officers were 78% male, 29% black, 19% Hispanic, and 4% Asian (Bohm and Haley 2018; Smith et al. 2017). Security guards generally receive relatively low wages, typically working 8-hour shifts, 5 days a week. Because of relatively low wages, private security officers frequently work part time or have another "primary" job and use their security job wages to supplement their incomes.

Issues of Private Security

Several unresolved problems and issues have been raised on the potential for further positive developments and roles of private security. First, legal status and authority of private security officers in many circumstances are not clearly understood, mainly because historically they derive from the rights of the owner/landlord who deputize security officers to protect property on the premises. Public police derive their rights and authority to act from a variety of statutes, court cases, ordinances, and orders enacted at various levels of government, are subject to public scrutiny, and have substantially greater powers than do security officers to arrest, detain, search, and interrogate (Bohm and Haley 2018; Fischer et al. 2019). But private security officers act essentially as private citizens, facing few constitutional limitations in their activities and being limited to the premises of their employer (see ▶ Security Guards: Authority and Power in this encyclopedia).

A second issue concerns security personnel's qualifications and training. Although many highly qualified individuals work in private security at all levels, they are not the norm. Private security fields and governments have attempted to regulate the private security industry and to increase the minimum qualifications for their officers, but security fields lag far behind those of the public police. All but five states –Colorado, Idaho, Mississippi, Missouri, and South Dakota – require that either private security companies or private security officers be licensed in some manner. In three of the states without licensing requirements – Colorado, Idaho, and Missouri – their largest cities, St. Louis in Missouri, Boise in Idaho, and Denver in Colorado, require security guards to be licensed (Nalla and Crichlow 2017). Though the majority of states require legal status in the USA (either US citizen or permanent resident), the minimum age for unarmed guards is 18 years old, and for armed guards, it is 21 years old; the minimum education level is at least a high school diploma or equivalent, and the minimum of formal training is at least 8 hours. Some large private security companies (such as Securitas and Wackenhut) have more minimum training requirements than what the states require in which they operate. The qualifications of proprietary security officers are generally higher than those of contract security officers, demonstrating that corporate is willing to pay a good salary in exchange for high-quality security services (Fischer et al. 2019).

A third issue is related to diminished public responsibility. The current cooperation of public and private protection is a matter of concern to many Americans (Bohm and Haley 2018). Some concern that since private security sectors have greatly expanded their protective services and roles, it seems that public police officers and the governments shift responsibility for protecting life and property to private security enterprises and default on a major portion of the social contract for domestic safety and protection. Still,

others concern the extent of roles and responsibility that private security can contribute.

A fourth issue concerns public policing in a private capacity. Many police departments prohibit moonlighting, but thousands of police officers still work in a private capacity during their off-duty hours with police uniforms and firearms. Some police agencies even cooperate with private agencies in scheduling their officers for off-duty assignments. One serious legal question with such an arrangement is whether these moonlighting officers are considered public police or private security officers. Another equally important question is who is liable if moonlighting officers abuse their authority or make a mistake (Bohm and Haley 2018).

Conclusion: The Future of Private Security

Growth in private security is shown by an increase in expenditures, employment numbers, and value of the equipment. Many new firms have entered security and protection business, established firms are showing strong growth, and some Fortune 500 companies and foreign firms are buying security companies. In a time when public law enforcement is experiencing little or no growth, private security directors are experiencing greater demands on their resources and professional expertise. The private sector has a tremendous impact on crime and the criminal justice system. The private sector will bear more of the burden for crime prevention and asset protection, while public law enforcement will narrow the focus of police services on crime control.

Both private security and public police need each other in order to be successful in sharing the crime prevention burden while protecting citizens, shareholders, and employees of a business. Interaction and cooperation between these two sectors are getting more critical and vital. Professional organizations representing private security would approach colleges, universities, and community colleges and ask for help with programs that train security officers and security professionals. More certification and education programs will be developed and offered due to increased demand for training and education for security officers.

Technological advances in security, including integration of computer and biometrics with CCTV (closed-circuit television) and access control protocols, should improve protection of assets. The combinations of biometric, electronic, and computer technologies in a layered approach will provide security and other management personnel to have effective and efficient surveillance. Integration of security technology is a continuing process to equip security guards and managers with smart cameras and wireless technology to provide real-time updates. Private security is increasingly becoming global, providing opportunities for security professionals. Private security is impressively optimistic and lucrative for the motivated person with a sound educational preparation, certification, and training (Fischer et al. 2019).

A variety of threats, such as active shooters and disasters, as well as natural hazards and man-made disasters, are constant challenges for security professionals. Active shooter situations that have become far too commonplace and the issue are complicated by the politics of gun control versus the Second Amendment in the US Constitution. Similarly, terrorism is another threat to both public police and private security. Since the 9/11 attacks, the private security industry and its officers have been given more protection responsibilities as the threat of domestic terrorism in the USA has increased (Fischer et al. 2019).

Private security officers are often the first line of defense against various emergency situations, criminal activities, terrorist attacks, and natural disasters in the USA and other nations. Limitations of the criminal justice system have been recognized, and the resultant void is being filled with some success by the private sector. The public sector cannot afford to pay for all of the protection needed in our modern and turbulent world. One formidable approach of providing protection and security is through the use of private resources that keep the costs of products down and provide an environment wherein our democracy and free enterprise system with social responsibility can be protected and progress.

Definition

Proprietary security refers to in-house security services, including physical, information, and employment-related protection of assets and personnel, provided by the company to itself through employees that it hires, manages, and trains (Nemeth 2018; Strom et al. 2010).

Introduction

Approximately 20 billion dollars are spent annually by firms across the world in a variety of sizes and segments who choose to develop and provide security as a proprietary or in-house function (Perry 2018). Often this decision is based upon the desire to have more control over the entire security operation and has much appeal to organizations that value loyalty, quality, and prestige of their security staff while eliminating the large rate of employee turnover often associated with a contractual security firm (McCrie 2016).

Where and how the proprietary security organization functions within the organization is a matter of great importance and shall determine its value and strength. There is clearly a thought process that suggests a proprietary security model is more expensive than a contractual model (i.e., outsourcing security; see ▶ "Security: Contract" in this encyclopedia); therefore, how it functions both operationally and financially has considerable significance. Unlike with the contractual model, there must be a designated security leader in the proprietary model whose function shall be to carry out security policy and procedures (Nemeth 2018). The degree and level of authority that the head of security (often a C suite position) or chief security officer (CSO) shall have will depend upon the level of need, importance, and vision the organizations' senior leadership has as it relates to the value safety and security it has to the overall organization as it continues to grow (Brennan and Mattice 2014; Finch 2013).

It is therefore incumbent upon senior leadership to establish goals and objectives properly which the in-house security organization shall be guided by to properly control spending while enjoying the best security outcomes (ASIS International 2012 as cited in Nemeth 2018). The CSO is held directly responsible for the performance of the in-house security department and must ensure his/her operation contributes to the overall asset protection model (see ▶ "Physical Security: Best Practices" in this encyclopedia). A strong synergy with the human resource department is valued as most recruiting, vetting, selecting, and hiring are handled in-house and through this department. Often state-mandated training and site-specific training shall be the direct responsibility of the security department (Reilly 2013). For large companies, interfacing with legal is also an important aspect of a proprietary security department.

Benefits of Proprietary Security

The obvious main benefit to proprietary security is control over personnel as the company handles its own recruitment, selection, training, and management (McCrie 2016; Reilly 2013). Secondarily, the benefits are that the highly qualified, career-oriented personnel are familiar with the specific needs of the company, are available on a consistent basis, and, as a result of receiving good pay and benefits, will be loyal to the company (Sennewald 2011; Strom et al. 2010).

Level of Employee Quality

According to Sennewald (2011), companies which have proprietary security are able to recruit personnel who seek careers, rather than merely jobs. Arguably the quality of an employee is determined, to some degree, by his/her rate of pay. In most cases, the proprietary organization has the ability to provide security personnel a highly competitive position by offering:

> salary, pension or retirement plans, profit sharing programs, the entire employee 'benefit package' (which usually includes medical, hospitalization, dental and life insurance, vacation, and sick leave), and employee privileges unique to the company (such as merchandise discounts in retailing and free or near-free travel for those in the transportation industry). (Sennewald 2011, p. 128).

The company, in turn, benefits by being able to hire a good-quality candidate, both in terms of the person's experience and education (Zalud 2007). Moreover, the proprietary security personnel are vested in the company, making them both ambitious and motivated to remain with the employer as they work toward promotion (Nemeth 2018; Sennewald 2011). As a result, the company has a stable and consistent work force, in whom it can invest time and resources knowing that improvement in security performance combined with dedication to the company will be the results (Sennewald 2011). The proprietary security personnel are technically proficient and share a comradery with the other employees. Reducing employee turnover is considered an asset to the company as the employment search process and training process are costly and time-consuming both to HR and to the security department (Reilly 2013; see ▶ "Security Guards: Academic and Training Programs" in this encyclopedia). The

organization treats members of the security department as it would any other employee, which allows security team members to have the feeling of belonging, something often absent in the mindset of a contractual employee (Zalud 2007; also see ▶ "Security: Private" and ▶ "Security: Hybrid" in this encyclopedia).

Control and Supervision

Being in direct control of security personnel is a significant advantage in the propriety model as the security manager and senior leaders in the company have dominion. Communication between the security personnel and the rest of the company employees is typically better because all of them share in common a mutual company identity and set of interests (Sennewald 2011).

The corporate security officer (CSO) is an essential member of the executive team, all of whom operate under the same mission to grow the company (Nemeth 2018). Unlike contractual security, the CSO of in-house security department will have a greater degree of control and supervision over employees (Zalud 2007). In particular, the CSOs and security managers are able to message the security team directly and quickly regarding the rollout of new or amended jobsite duties, change in security direction, a disciplinary concern, or simply a special one-time requirement. This streamlined approach is clearly a time-saver as the same message when contract security personnel are used would need to first go through that organization prior to getting filtered down to the applicable officer(s) for implementation. Additionally, in-house security managers are able to perform the necessary task of daily supervision of the security staff, allowing them to make immediate corrective action should a violation be detected (Nemeth 2018). In a contractual model, staff violations would often first be reported to a central location for determination, which is time-consuming and does not allow for adjustments to be made at the point of concern in a timely manner. The CSO must also oversee a program that will teach its security personnel about risk evaluation and security training at hire and periodically afterward to maintain a high standard of competence and upgrade their skills (Reilly 2013). Although organizations using a contract agency can include verbiage in their contract to allow them to remove guards, it is not a common practice.

Loyalty

Employees who enjoy longevity in their tenure with a company are often also loyal to it; this same philosophy can be applied to proprietary security personnel. The security team identifies with other employees in the company, and all of them will feel pride and self-admiration when the business grows and succeeds as a direct result of their dedication and hard work. The level of reliance placed upon proprietary officers to perform their duties is often heightened due to the level of familiarity with the organization and how the business model functions (Zalud 2007). These employees are integrated into the company's culture and value system, accepted as members of the group, and included in business functions, such as holiday parties and other celebrations. This type of treatment fosters a great sense of belonging as proprietary security are looked upon as equal members, that is, like any other employee in the firm (Sennewald 2011). In this way, the CSO is able to gain the team's acceptance, support, and compliance in security-related matters for the company, actively involved in supporting company interests (Nemeth 2018). The CSO will also give preferential treatment of the security officers since as a team they provide protective services to assets and personnel. They may be given a higher level of consideration when requesting compensation and time off because they are expected to assume a great deal of responsibility and have earned the respect of the company. With a contractual firm, longevity of personnel at their jobsites is atypical and often only occurs with the most determined and dedicated employees. Due to salary disputes, transportation issues, level of responsibility, and shift assignments, turnover can and often will affect contract security employees' length of stay at any one venue. Hence, these officers are absent of loyalty because they simply do not have any feeling of value to the jobsite other than the proper

performance of their duties (Sennewald 2011). Some security professionals consider the disconnect between employment and loyalty the most considerable contrast between the proprietary and contractual models and often one of the major considerations when deciding on which security business model best fits the needs of the organization.

Prestige

Many CSOs or corporate senior leaders prefer to have their own in-house security team in place because they believe it gives their organization a level of admiration and prestige. Secondarily, they believe developing a unique and specialized security system (both physical and technological) for the sole purpose of protecting the people and property of their organization is necessary (Nemeth 2018). In a conceptual sense, there is clearly an underlying thought that an in-house security department is more highly regarded and run with a greater degree of professionalism than could be offered by a contractual firm (see ►"Maritime Security: Armed Guards on Board" in this encyclopedia). The downside of this model is a considerable increase in spending, compared to the stable and known expenditures of contractual security, which may be overlooked in the organization's goal to project an optimum level of status.

A sense of prestige and importance also becomes embedded within the security office. Working for a well-known and globally recognized organization is clearly more prestigious and seemingly more important than working for an unknown security firm (see ►"Security: Contract" in this encyclopedia). The fact that a uniform displays the name of this well-known organization rather than that of a nondescript company may be a source of pride for security officers. In particular, when those in the security industry have the opportunity to congregate and discuss their employment, a boastful tone may be associated with certain firms and locations over others. This sense of pride should not be dismissed as it leads to employment longevity, a significant degree of caring and ownership that the work is impactful, and provides security officers with a sense of importance.

Financial Impact

Arguably the proprietary security model is more costly than the contractual security model as the in-house firm is responsible for all HR-related issues. Specifically, the proprietary organization is responsible for screening and vetting, training, supervising, and managing the officers and providing security-related equipment (Sennewald 2011). Conversely, the degree of loyalty expressed and the feeling of prestige felt by security officers often bring with it a high degree of retention, reducing the significant level of turnover often associated with the security industry (Zalud 2007). This might not balance out the additional expenditures with this model, but clearly retention becomes a cost-saving tool that allows many firms to continue to use an in-house team. Other items, such as payroll-related taxes (federal, state, local along with unemployment taxes), uniform expense, overtime cost, vacation allowance, and in-service training, all become the burden of the proprietary organization (Nemeth 2018).

But often the largest financial burden an in-house organization must cover is that of liability and personal injury exposure. In the proprietary model, the company is susceptible to a variety of liability risks during the performance of security officers' daily routines. Items such as errors and omission, personal injury, false arrest, assault, and battery and property damage all become the responsibility of the in-house firm, should security officers make egregious errors while performing their job site duties (Nemeth 2018). Additionally, workers' compensation insurance (unlike liability insurance, WCI is generally required in all states) provides benefits to employees for work-related injuries or illnesses, which include medical care, wages due to lost work time, and benefits to families of deceased workers as well (Nemeth 2018). Accompanied with providing liability and workers' compensation coverage comes the added risk of increased premiums, should the firm experience exposure to one or both of these necessary forms of insurance coverage, such as

when a claim requires the underwriting insurance company to provide monetary satisfaction.

Conclusion

Ultimately senior management of the proprietary organization will have to determine if the potential increase in effectiveness and efficiency is outweighed by the projected additional financial burden of providing an in-house security unit. Evaluating the need(s) to expand as the organization grows both in size of employees, and expansion of their facility must also be a strong consideration. Management must recognize that security-related concerns, either real or potential, often require the expansion or enlargement of the security operation, but associated costs should not influence this decision. Finally, and often overlooked in this model, is that many states do not require a significant level of oversight to an in-house security operation. Regulatory concerns, such as hiring someone who holds a particular state security license, are typical of contractual security which vends its service to others (Strom et al. 2010). Simply registering your firm as an in-house security operation with the applicable state is usually sufficient. Furthermore, security officers in some states do not need to register with the applicable licensing body or go through any level of mandated training, streamlining the hiring process (see ► "Maritime Security: Armed Guards on Board" in this encyclopedia). Proprietary organizations must decide what level on screening and training shall be considered adequate.

What Is Security Theory? – The Definition

Security theories are perspectives on security, based on different epistemic backgrounds.

What Is the Core Concept of Security?

Though an average citizen usually thinks first about security in terms of social and public security, when we discuss the meaning of the concept in theoretical terms, security has its own meaning in different disciplines. Though some features are definitely common with social security or issues applied to various law enforcement problems, in Security Studies, the core subject of it seeks to explain and to identify the causes and to anticipate the likely consequences of events considered as a security issue (Collins 2016). While social security is generally linked to the internal order of social coexistence (to guarantee life, wealth, and rights of the individual), public security, job security or social justice, the concept in security theories, is rooted in the traditions of politicization. Before we turn to specific examples of security theories, it is necessary to introduce the most important concepts that have influenced security studies development.

Introduction

Originally, the term "security" itself (as did the German "die Sicherheit" or the French "Securité") comes from the Latin words "sine cura," which mean "without danger" or "without threat" (Gazdag 2011: 11). After its widespread use in the late 1940s, the word 'security,' regardless of its complexity, established a narrow definition in international security studies as a sub-area of international relations. The original term implies a negative approach that makes security equal to the absence of danger and threat. However, other approaches emphasize a positive definition of security, thus emphasizing the existence of factors that contribute to maintaining or establishing security. The term security was originally defined as a set of political goals, strategies, and tools that serve to prevent war while maintaining the ability for political self-determination. Its objectives are "to protect the political independence, territorial integrity and economic viability of the State, to ensure the security of its citizens and the development of their personalities." (Ritch 2001: 33). It should be noted, however, that security studies are not the same as strategic studies, which mainly deal with the use of armed force, and, therefore, it covers a much narrower area than security studies (Colins and Cohen 2007). The use of definition here corresponds to the Anglo-Saxon scientific discipline.

According to the collections edited by Collins, Ian Bellamy defines security as "relative freedom from war"; Walter Lippmann thought of security as a situation in which the nation does not have to sacrifice its key interests; However, Arnold Wolfers defines security in economic, cultural, and moral terms and considers it as a lack of fear, in terms of fear that aquired values would be at risk. Also, in Ken Booth's definition, security is interpreted as the freedom of people to do whatever they want without any physical or human compulsion. From all this "definition clutter," it can be seen how difficult it is to formulate what it means. Instead of choosing one of the definitions, it is advisable to accept the heterogeneity of the area and emphasize the inherently versatile nature of the concept of security.

Looking broadly, security theories deal with how to ensure the security of individual entities, the security of a nation, considered as the most important guarantee of which is the state. In our globalized world, this may seem anachronistic, but states are still considered as the key players in an international strategic environment. Shortly, security theories provide scenarios for how political actors' work can affect the security of an entity. The entity to be provided called the "reference object" might be interpreted on several levels: for example, cities, regions, nations, states, the international system, or even the security of the entire planet. Hence, the limitations considering the objectivities and conceptual framework of security studies are still a highly debated issue.

It should be emphasized that the concept of security has radically widened in the last decennia, broadening from purely military to a more general formulation. Currently, there is no sharp distinction between domestic and international security, and the boundaries of external and internal security are often blurry, especially due to increasing amount of non-state actors such as corporates and NGOs engaged in security field today. Security theories thus explain through abstract models how to ensure the security of some reference objects, such as a nation, and like most theories, address the question about how our reality works and how to define the impact of security issues to reality. Furthermore, most theories also give normative guidance to the actors on how to handle the various specific procedures in this reality (Baldwin 1997).

Recent Security theories are shaped by several disciplines including social sciences, political science, economy, and policing studies. As a subfield of international studies, Security studies is established after the First World War, following the establishment of the Department of International Politics at Aberystwyth University, United Kingdom (Williams 2012). As an independent scientific discipline, it only appeared after World War II, with some major achievements related to the appearance of nuclear weapons and the possibility of an outbreak of a thermonuclear war. Such changes increased the recruitment of civilian advisors in foreign and security policy, an area previously dominated by military personnel, also thanks to the recognition of the need to exercise civil and political control over nuclear power (Buzan and Wæver 2007). These developments shaped several epistemic schools in security theories that are still represented today. In the following outline, three main theoretical streams are presented – realist, liberalist, and constructivist approaches – and how new objectives are evolved in these thoughts till today. It should be noted that all three theoretical traditions involve different security models – for example, the theory of deterrence and the theory of balance of power is also connected to realism. Hereinafter, all three will be elaborate as well as the different theories and models within certain trends.

Realist School

There are two positivist approaches in security theories encountered under realist and liberalist objectives. These are generally focusing on geopolitical power structures in comparison to the constructivist critical theories. The first scientists working on security theories are the so-called Realists focused primarily on deterrence, targeting, deployment, and impact measurement.

Realism has its roots in theories of Niccolo Machiavelli and Thomas Hobbes, who consider states as responsible actors to maintain law and order and security (Wheelan 2004). According to this approach, international institutions are not major players, states are the most important actors in the international order, and only the right balance of power can ensure international order. This political realism paradigm was originally based on three main attributes: "statism" whereby the state is the most important player in international relations, in which "survival," the maintenance of the essential needs, is the fundamental interest of every state, and finally "self-help," which refers to the behavior of states, since states are forced to guarantee their own security (Lippmann 1944). The ontology of realism is the state, especially the behavior of the great powers in which states act in their national interest and in order to preserve their own security. Therefore, they seek to increase their power in the international system. Power is therefore one of the central elements of realism.

Realists in security theories, however, take a very pessimistic view of human behavior in this regard, by assuming that states generally do not trust each other. This means that states pursue their own national interests and do not trust other states of the international system. This skepticism is rooted in the experience of the two world wars after which political realists felt that their theories were validated. This epistemological trend is built on a positivist methodology – an approach that emphasizes normative scientific measures. Accordingly, states are considered to be rational actors who always choose the option with the lowest cost but provide the greatest benefit, so they can develop their own central power structures.

Realism carries with it the logic of anarchy, which is nothing more than international conflict. Conflicts are always associated with the disruption of the international balance of power. Where the balance of power is restored, stability and peace will follow. Most realist thinkers believe that anarchy is directly linked to the proper distribution of power and at international level it produces a certain type of order. Realism holds that

> in the pursuit of foreign policy, the state must draw upon the society and economy for material resources and political support. In effect, the state's external policies depend critically on what it can extract from its domestic system. In the pursuit of foreign policy, the state finds itself giving great attention to strengthening, shaping, and developing domestic material and political resources. The sources of national power are many-political, economic, and military. " page 460 Toward a Realist Theory of State Action Author(s): Michael Mastanduno, David A. Lake and G. John Ikenberry Source: International Studies Quarterly , Dec., 1989, Vol. 33, No. 4 (Dec., 1989), pp. 457– 474

Yet, as realists believe, there is no such a structure in international relations as global government, but the lack of superior power does not exclude the possibility of an international order.

Security Dilemma

In the 1950s and 1960s of the Cold War with political tensions between the United States and the Soviet Union, government funding was available for major research projects. "In the context of the mutual nuclear threat between the United States and the Soviet Union, and the massive military capabilities of both the North Atlantic Treaty Organization (NATO) and the Warsaw Pact, it was necessary to seek ways of enhancing one's own security. Nuclear states tried to reduce the threat of their potential opponent without necessarily military measures, and to maintain the overall stability of the international system. For most of this period, however, the content of security was seen as exclusively military security against the military power of other states" (Buzan and Wæver 2007: 114). In this period, many security researches stayed initiated in the United States, particularly at RAND Corporation, which was originally a so-called US Air Force Research Center think tank. RAND has developed interdisciplinary approaches, such as the application of game theory and system analysis for a better understanding of the different nuclear strategic and security issues. In this period, many researchers from a variety of backgrounds were involved in security studies like mathematician Albert Wohlstetter, Thomas C. Schelling educated in economics, Bernard Brodie who taught political science, and even Henry A. Kissinger who was a historian. This boom in the theoretical development resulted in several new security approaches (Baldwin 1995).

There are two main objectives that shape Realist theories, offensive and defensive security approaches. Offensive realism has the similar structural logic as defensive realism; therefore, it is also called as the "little brother" of neorealism. In the offensive realist view, it is anarchy and insecurity that compel states to keep searching for opportunities to increase their power. To this end, they are also willing to risk the status quo and, if the opportunity arises, become a hegemon, for them the safest position (William 2008). This theory is mainly linked to the publication of John J. Mearsheimer entitled *The Tragedy of Power Politics* (Mearsheimer 2001).

The more popular approach among realists is Defensive realism, claiming that cooperation of states is not possible. Representatives of this theory like Robert Jervis and Charles Glaser and Stephen Walt introduce subsystem factors (such as internal political factors) in security theories (Smith and Fontanel 2008). According to them, the conquest in power structures is very complicated, so the states prefer defensive than offensive policies. Hence, defensive view can lead to a security dilemma, that was originally conceptualized by John H. Herz (1950), who set out such defensive reasoning of states in a relativist approach. In a simple way, he describes how state A would increase its military capabilities, that triggers state B to do the same, as it wouldn't feel safe and will follow suit. Accordingly, state "A" forces "B" to continue arming, which also puts state B in the direction of further militarization to increase her security. This arms race is increasingly destabilizing and can easily lead to

international conflict. According to realist literature, this process has led to World War I as a classic example. Shortly, due to the distribution of the relative abilities of security actors, there are major powers (poles) in the international system (Balogh 2013), as states have different recourses to increase their abilities. The theory includes a very interesting and controversial aspect: although both states had separately increased their own security, overall, they became more precarious, because they couldn't be sure of the other's intentions. Thus, according to the theory of the security dilemma, war is possible even if the two sides have increased their military capabilities purely for defense purposes, not with offensive intentions. This is a great representation of the states' lack of trust in a state of anarchy that dominates the international system (Booth and Wheeler 2008). Though states are very similar in that they see the same functions, their abilities are different and that is what defines the structure of the anarchic international system. Anarchy forces states to act on their own to protect their interests, and this results in an "involuntary" articulation that imposes rules on states' behavior.

Neorealism

In line with Defensive realists' theories, several objectives have been developed, such as structural realism, or with other terms neorealism. In his *Theory of International Politics (1979)*, Kenneth Waltz explores the central question: why do states with different political systems behave similarly in the international system? According to his theory, states' policies are determined by the constraints imposed by the international system. Waltz also challenges traditional notions of power by referring to cultural, economic, and political attributes. Therefore, the most important classification in Waltz's work is the distinction between "reductionist" and "systematic" theories (1879: 60).

Reductionist theories focus on unit-level variables (such as the state), but systematic theories focus on the system and prioritize system-level variables (like power sharing). As it is based on the analogy with market theory, Waltz's book focuses on the latter and explores how the international political system works. The market, according to Walt, is like international and economic operators, and those are equivalents of states. The market has certain laws. If an actor wants to remain competitive, they must follow them in order to avoid bankruptcy, which would force others to leave the market. Similarly, the state must obey the anarchic laws of the international system in order to survive. So, in order to remain competitive, the states need best practices in the system to maintain security. The system itself determinates competitive elements by rewarding certain forms of behavior, while punishing others. States learn to adapt to these rules through socialization and constant competition. The system is made up of units and their interactions; although, the system itself is determined by three factors: the order in which the components are located in the structure (anarchy or hierarchy); and the functional specification of units (states), which indicates units how and with what intensity they can perform their functions.

The Theory of Power Balance

Hans J. Morgenthau is considered the most respected theorist of modern realists today with his book *The struggle for power and peace* that was published in 1948. Morgenthau believed that the driving force behind politics has always been objective laws and human nature. The most important objective law is the idea of interest, defined by the system of concepts of power. In his theory of balance of power, Morgenthau explains thus how states balance each other's power. The balance of power is always shaped by sovereign states, following Max Weber's logic, who have a monopoly on legitimate violence. States possess weapons because of their inherent inclination conflict, so depriving them of their weapons would be futile because their willingness to stays involved in conflicts. The theory also distinguishes internal and external balance. The former refers to the internal activity of the state to increase its power and capabilities, and the latter to the establishment of alliances (Balogh 2013).

Realism recognizes the moral consequences of politics, though states' policies cannot be

governed by a universal moral code (Booth and Wheeler 2008) Accordingly, Morgenthau assumes that individuals are rational, so that their actions can be calculated within certain limits. All kinds of politics (including international politics) are defined by different actors by the effort to maintain and gain political power. He explains that security politics must be interpreted as an autonomous balance of powers that forms a coherent system. This system may include alliances or subsystems, which have their own regional power balance formation. It is held by states to maintain stability in the international system by preventing individual states or the emergence of groups of states that could endanger the security of other states. Furthermore, they control the power positions of other actors; sometimes an alliance even coordinates their activities. However, peaceful social change rarely happens and, as most realists, Morgenthau is skeptical about the role of international institutions, especially with regard to the UN. As states are constantly striving to prepare for war and the factors that upset the status quo almost always lead to international conflict, political realists always monitor the relative power of a nation and its position in the international system. This means that power must always be measured in relative terms.

The theory of threat equilibrium is a modified version of the former approach. In this theory Stephen Walt developed in *The Origin of Alliances* (1987), he claims that states control threats rather than power.

> "Walt argues that states take action to counterthreats to their security with threat level determined by four characteristics of a possible rival state: 1) aggregate power, 2) offensive power, 3) proximate power, and 4) offensive intentions. To the defensive realist operating according to balance of threat logic, the threat to state security comes first and is followed by a counterbalancing reaction. This contrasts with the offensive realist assertion that great powers are primarily assertive – not reactive – in efforts to expand their power" (Person, 2017: 45).

Although the theoretical approach of Walt was an important step in the development in Security theories, the main objective was still a positivist, narrow, military force–based approach on interstate level. With the rising dominance of liberal political paradigms, liberal security theories have gradually extended the scope of this field.

Liberalism

The events of the 1970s and 1980s brought about a significant change in the role of security studies compared to the early years of the Cold War. The oil crises emphasized the importance of interdependence and the role of international economy in security theories and justified the non-military dimensions of security and the corporate international system. This economic-political shift is raising the relevance of liberalist theories and the role of interdisciplinary studies in security theories. Epistemologically, liberalism takes a positivist approach like realism, but liberalism accepts the erosion of state autonomy if it contributes to the well-being of its citizens. The classical liberal approach in liberal political philosophy relies on Locke, Hume, Smith, and Kant (Ferenc 2001). Ontologically, instead of emphasizing the importance of the military power of a state, it emphasizes the importance of economic policies and cultural values and rejects that power politics shape international systems. There is not much skepticism about the cooperation of different actors as Realist have, but liberals also emphasize the mutual benefits of international cooperation with the participation of non-military organizations such as NGOs or commercial firms, as influencers of security politics. Thus in opposition to Realists, liberals believe that international trade makes international cooperation possible, and therefore to reach goals like peace. The United Nations and other organizations are also recognized as core actors contributing to international relations and stability. These organizations are considered as mitigating, that reduce uncertainty and have a stabilizing effect on the international system (Morgan 2007).

Collective security is one of the core concepts of liberal security theories. Collective security is a regional or collective agreement in which states guarantee their sovereignty and security. They reject international aggression and seek to resolve

their disputes by peaceful (diplomatic) means. A collective security system is supported and managed by international institutions (Roberts and Kingsbury 1993). It is based on the notion that security is indivisible and that a common response to aggression is needed.

A well-known liberal international security theory is the democratic peace theory, basically related to Michael Doyle and Bruce Russett et al. (1995). They assume that democratic states are not at war with each other. Doyle also mentions international relations' three different representations of the liberal viewpoints: the first is an interpretation of Locke, the second focuses on the importance of international trade, and the third is the Kantian concept of peace. Locke's interpretation accepts the concept of anarchy and takes into account the possibility of conflict. However, in his view, one of the most important attributes of the state is legitimacy, as it is based on representation. The second idea is international trade and the stabilizing role of capitalism, that is what generally promotes peace. The Kantian concept is based on the philosopher's idea of "eternal peace," the idea that to achieve eternal peace we need an alliance of republican governments. He also states in theory that although democratic states are not at war with one another, they are often ready to provoke non-democratic states (Doyle 1983). Michael Doyle distinguishes two approaches to the rights and freedoms of the individual: liberalism of 'laissez fair' and 'social welfare'. The first refers to the limited role of the state that advocates individual citizens' freedoms and free markets, while the 'social welfare' approach is much more in favor of expanding the role of the state for welfare purposes. Doyle distinguishes three liberal forms in international relations: distinguishes a great liberal tendency. The first is the "liberal zone of peace", which implies that liberal states generally have greater legitimacy and are thus willing to cooperate with each other, which creates the right conditions to peace.

The second trend raises the "reckless aggressiveness" of liberal states against non-liberal states. While liberal states would be less willing to risk a war against each other, non-liberal entities would fight at any time. The third approach is referred to by Doyle as "leniency and isolationism," referring to the occasional behavior of liberal states, when they are not willing to defend their allies or confront the aggressor. Examples include Nazi aggression before and during World War II and policies based on Western reconciliation.

Neoliberalism and Interdependence Theories

The above theories emphasize that a state's internal political system defines its foreign policy. This epistemic standpoint is in stark contrast to the ideas of neorealism, which are based on states being rational powers and seeking to maximize their security by acting in their own national interest, leaving out the quality of their internal political system. Robert Keohane and Joseph Nye's book *Power and Interdependence* (1977) developed a so-called complex interdependence theory, an opposing of the aforementioned approaches.

Keohane and Nye distinguished two forms of relationships: sensitivity and vulnerability. Sensitivity refers to how quickly certain political changes in one state are affected by others. Vulnerability, in turn, expresses the existence of such an alternative policy solution that addresses the negative effects of sensitivity (Azar and Moon 1984). In similar terms, liberal institutionalism emphasizes that international institutions and regimes have the power to shape international politics and international relations as well as states. International institutions are the starting point of the state activities, which follow certain standards, in particular international law rules. These institutions reinforce trust between states and facilitate agreement to sanction players who do not play by the rules. Keohane says they are also good for solving the security dilemma.

According to this theory, regimes are just as important in maintaining the stability of the international system as democracies. In Stephen Krasner's words, regimes represent "rules and decision-making procedures in a certain area of the international relations, around which the expectations of the actors can converge" (1983). Regimes control different international areas, focusing on a specific issue, such as non-proliferation. They help to reduce uncertainty, can

influence states' actions on a particular issue, and are predictable and they can also make the actions and intentions of other states transparent (Dannreuther 2014).

Another theory of global governance is linked to James Rosenau's name (1992). He claims that even if global government is not possible to establish, global governance itself is feasible with international institutions, regimes, NGOs, states, and so on. A global network of these actors can counteract the lack of global power. Shortly, the institutions of a world-wide network of regimes and other actors determine the rules needed to govern the spheres of international relations and provide a sense of stability (Rosenau et al. 1992).

Integration theories overlap with certain liberal institutionalist theories. According to integration theories, security can best be guaranteed by the integration of different policy areas and actors. Integration institutions (such as European Community) give impetus to further development and the integration process itself as well as playing a central role in integration theories such as neofunctionalism. Ernst B. Haas and Mitrany are the founding thinkers of neofunctionalism who outlined the global integration of different political functions primarily in the technological, economic, and social spheres. According to the theory of neofunctionalism, various interest groups in a particular political or functional area have a cross-border dimension where links are established to further the integration process. If one functional area has been integrated internationally, this integration has a so-called spill-over effect on other areas, and so in some areas leads to gradual unification (Rosamond 2005). In this way, the theory is closely linked to the European Union, as the history and development of European integration is often examined through the lens of neofunctionalism (Haas 1975).

Liberal hegemony is a liberal version of hegemonic stability theory. According to this concept, a liberal hegemon serves the interests of other states in the international system by promoting liberal values. Like realist hegemony theories, liberal hegemons provide public goods such as security, order, etc., but the most important common good it has to offer is the spread of liberal values (Collins 2016).

Human Security

During the Cold War, national security strategies were primarily territorial and against threats from the outside with a government and an army considered as responsible for guaranteeing human safety. In contrast, over the past two decades, new frameworks are developed to adjust the scope of security objectives as more and more new security challenges were difficult to conceptualize within the earlier prominent tools which become inadequate to deal with these changes. One of these approaches is the so-called human security theory, which proposes a people-centered approach instead of state-centered security concepts, with the emphasis on protecting individuals. In his new theory, the scope of the investigation is extended by new elements in terms of actors and tools. The concept of human security focuses not only on defense, but also on prevention (rather than on the generally defensive nature of military security based on arms race and strategic alliances). The first milestone in the development of the theory of human security is the Human Development Report (UNDP 1994) that first drew attention to security *and* development due to a large number of conflicts within states which were taking place in the form of civil wars, not between states. This approach is in stark contrast to the ideas of realism, which considers states as the basic unit of security (reference object). According to the theory of human security, the individual must be the reference object and every factor that endangers an individual, either physically or psychologically, should be understood as a security threat. This is especially true if we take into account that sometimes the state poses a threat to its own citizens. By explaining such situations, this human-centered approach introduces new difficulties for positivists, because this theory calls into question the state-centered views of realism and is therefore bound to constructivism and critical security studies (Kerr 2009).

In theoretical terms, two academic groups made such broadening efforts. In one new approach, the novelty was provided by the expansion of security policy actors. According to this group, the key to understand new types of conflicts, such as terrorist attacks, is not about loyalty to states or conflicts between them, but a clearer understanding of the identity circumstances behind "sub-state violence" ("blood and belonging"). It should be noted, however, that this group is probably rightly criticized for defining the various forms of irregular and asymmetric wars and terrorism today as a new type of conflict. According to this criticism of the non-state protagonists, these events should not deny the Clausewitz conceptual framework, namely that war is the pursuit of politics by other means. Accordingly, there is always political intent behind civil wars, ethnic and religious conflicts or terrorist acts, but the actions are not security issues, they are simple law enforcement and criminal law issues.

Other theorists argue that challenges, such as cross-border organized crime, necessitate greater involvement of non-military threats in security studies. This has led to the concept of human security today. It is now more or less generally accepted that beside state actors in international politics other actors are also playing an increasingly important role in the international system. Non-state actors such as multinationals, terrorist organizations, environmental organizations, international foundations, civil and church organizations, or non-state nations, such as Kurds, can also create and develop their own private and non-governmental security policies. Multinational companies, especially since the 1990s, are increasingly relying on private military and security companies to protect their interests. Our globalizing world is now accompanied by global terrorism. Democratic societies are increasingly forced to take into account these international actors like reports of Amnesty International. These power relationships would result in less conflict and greater stability at national, regional, and global levels. Thus, on the one hand, the focus shifts from the state to the individual, but on the other hand, the scope is different: the classic concept of security that states protect against external aggression is challenges, and in human security this concept is complemented by wider threats, such as pollution or epidemics. Instead of the state's exclusive role (decision-making and monopoly on violence), "non-state actors play a key role in providing security" and as a result the fundamental concept of security is reworded and expanded (Newman 2010: 78).

So instead of territorial security, the focus should be on the security of the individual, and on the concept of (sustainable) development instead of weaponry. Thus, the concept of individual security has shifted toward meeting needs, and as a result, human security has been linked to economic development. However, the report emphasizes that human security is not equivalent to human development. Development is a broader concept, and its main goal is to provide people with more choices in all areas of life. In contrast, the concept of human security is a broad one, seeking at enlarging individuals' choices by "assuring priority freedoms so that 'people can exercise choices safely and freely' (HDR 1994, page 23) and can be confident that the opportunities they have are protected" (Gomez et al. 2013). Consequently, there is a kind of interdependence between the two areas that the failure of one area is likely to have a negative impact on the functioning of the other and is likely to accelerate its decline. Indeed, over the past decades, putting the theory into practice has led to the emergence of two schools, one of which is attributed to each of the major threats, both taking (the lack of) freedom as a core starting point.

Hence, in the economic sector, it is much more difficult to identify the real threat than in the military and political sectors. In the social sector, it is primarily nations, ethnicities, or religions that may be threatened. However, since community identities are constantly evolving in response to external and internal influences, it is often extremely difficult to draw clear boundaries and distinguish between a life threat and a lesser threat. If our identity is more conservative, we are also more inclined to regard some of these natural changes as a threat to our identity, even when others do not experience the changes. For

example, the ability to maintain language, behavioral habits, or ethnic purity is generally regarded as survival, and the loss of this ability is a threat to life, although the latter may have a different meaning (Kaldor et al. 2007).

As far as the environmental sector is concerned, there are quite obvious cases at both macro and micro level that can be secured. The survival of a species or habitat, in more general terms, the biological heritage of mankind, a change in the usual climatic environment, and the maintenance of an advanced level of human civilization can be interpreted as security issues. However, like the economic sector, we find a set of problems in the environmental sector that are much more difficult, though not impossible, to formulate as a threat to life. As it will be illustrated, this widened conceptualization become very popular among constructivists, and critical theorist emphasize that it should be situationally reconsidered whether a given question is really a security issue or something else. In summary, the threat to security – that is, the factors that negatively impact security – is seized with the concepts of threat, potential threat, and risk and national security strategies (Brauch 2005).

Constructivist Approach and the Critical Schools

New security challenges after the Cold War gave new incentives to think in security theories. The United States and Europe followed a different path in these developments after 1980s and 1990s. European security studies are much more inclined toward international security issues, more critical, and in contrast with positivists; it is established on the constructivist (Neo)Marxist approach. North American scientists use a more traditional theoretical perspective and US experts have remained more closely involved in political decision-making. In Europe, there are three main schools registered within the framework of Critical Security Studies: the Paris School, the Whales School, and the Copenhagen School. Based on these reflective approaches, recent Critical Security Studies inspired many academics and experts who left conventional positivist security frameworks (Realism and Liberalism) to gain a better understanding of contemporary (in)security issues. Also, many recent theories elaborated Security theories with engaging other disciplines and progressive radical theories, such as critical feminism or environmental theories, as well as Neo-Colonialism or Race theories. Before the different schools would be elaborated, it is important to highlight the main epistemic difference between the previous Security theories and the Critical.

As the core epistemological foundation of Critical security theories, (Neo) Marxism deals with certain aspects of material reality, though it tends to question the status quo and power order, both at the sub-state level and internationally, which already entails a kind of criticism. The original theory is linked to the work of Georg Wilhelm, Friedrich Hegel, and Karl Marx. Marx, in his 1867 book, *Capital,* he expressed his views on privileged social classes with appropriate certain resources, such as capital. Marx argues that the capitalist class benefits from withholding wages because they keep to themselves the difference between the value of the work produced and the wages actually paid. According to Marx, the means of production are in the hands of the capitalist class, so it is a privileged position that creates tension between capitalists and the working class. All social relations and society as a whole, with all its subsystems ("superstructures"), are based on the economy ("basic"). Neo-Marxism is associated with Antonio Gramsci, who emphasized in his works that the state and the ruling class are in a hegemonic position within society that can only be sustained through the cultural hegemony of capitalism (Fontana 2008). Robert Cox is one of the most influential Marxists in international relations. Cox used Gramsci's theory to the international system and explained that the international capitalist class maintains its international hegemony through the culture of capitalism. So, Marxism focuses on transnationally connected and organized departments and class interests in place of military power of nation states (Cox 1987). Another well-known neo-Marxist interpretation is Immanuel

Wallerstein's "world system theory", which Wallerstein based on his early work. In his view, capitalism is a world system made up of three types of entities: an economically advanced center (core) that dominates the entities belonging to the semi-periphery and the periphery.

The latter mainly provides cheap raw materials and also cheap labor for core areas and as a market services the core technology of modern products.

The core area retains its economic and political priority through its economic relations with the periphery and the periphery. The semi-periphery is a mixed category of entities that strive to catch the core while the states of the periphery try to join those at the semi-periphery. Neo-Marxist thinking is very similar to Constructivism considering the ideology on the monopoly of power or system of norms that is interpreted by the result of its core function, namely to maintain the power of certain classes and through generations of hegemony and social status reproduction (1974).

Constructivism arose from the transposition of critical theories into political science, sociology, and philosophy in international relations. In these disciplines, Constructivism is closely linked to the Frankfurt School and its renowned scholars such as Theodor Adorno. According to Michael Barnett, in order to understand how different ideas, ideologies, and power structures are played out in different contexts, all types of political power acts and statements must be broken down in order to better understand reality. This view in international relations had a peak between the 1970s and 1990s, and was associated with, among many others, Peter J. Katzenstein and Alexander Wendt. In their view, the national security environment of a state and security politics is primarily determined by cultural and institutional aspects, and non-material elements such as collective values, culture, and social identities. They thus determine the identity of the state, which in turn is decisive in shaping state policy. Accordingly, "international reality is socially constructed by cognitive structures which give meaning to the material world" (Adler 1997: 250).

According to a constructivist interpretation of Wendt, international politics is thus a construct that reflects a certain type of shared knowledge and a set of norms about reality. These norms are the result of the interaction of actors in the international system. Identities are built through interaction, and these determine the interests of the states – so the national interest is a construct. This however influences the actions of the state and material reality too. The central role of ideals and norms is what is essential for the international system to understand its structure and the behavior of states (Wendt 1999).

The Welsh School

The Welsh School (or Aberystwyth School), also known as emancipatory realism, is differentiated from the other critical schools by exclusively requiring Critical Security Studies (CSS) as the theory of studying security issues (Peoples and Williams 2014: 14). By combining Radical International Relations Theory with Critical Theories – based on the Frankfurt School and Gramscian thinking – academics Ken Booth and Richard Wyn Jones distinguished their approach from other critical approaches below (Peoples and Williams 2014).

They do not only reject the realist scope that considers states as the key security referent (defective, irrational, and too distinct) (Booth 1991: 320), but also reject the Copenhagen School in their supposition that only the threats of security are socially constructed, while the security objects are stable (Buzan et al. 1998). From the CSS viewpoint, both threat and object are social constructs (Mutimer 2016: 95).

The CSS believe that the inter-subjectivity significantly determines the variety of perspectives in security concepts that further construct it as a contested concept (Collins 2010: 3). According to these authors, security is what we define as such. This contested inter-subjective definition of security also challenges the Human Security approach in how it defines security (Lum et al. 2018). In the core, security is based on the set notion of the protection of all essential parts of human lives from any decisive and persistent dangers (Balogh 2013). Emancipation of this inter-subjective security is the only way to achieve the real security and the freedom of anyone or any group from any threats that restrict their free will

to choose what to do (political repression, deprived education, poverty, etc.) (Booth 1991: 319).

The Paris School

Another important critical school, studying processes of (in)security and (in)securitization, has been established by the so-called Paris School scholars. "PARIS is an acronym for Political Anthropological Research for International Sociology" (Bigo and McCluskey 2018: 116). The most prominent member of the Paris school is the French sociologist Didier Bigo, who has been joined by a number of likeminded scholars such as Laurent Bonelli, Ayse Ceyhan, John Crowley, Anastassia Tsoukala, all of whom place great emphasis on the utility of Foucault for the study of security (Bigo 2005). Bigo highlights "how different bodies of knowledge are labeling security, examining the tensions and controversies between and within practitioners and disciplinary fields in these labeling practices. It analyses different intellectual ways to study the relationship between the "security" label and the boundaries of "security" practices alternatively labelled by others' freedom, mobility, violence, or privacy" (Bigo and McCluskey 2018: 116).

This school treats security also as a social construction, opposed to an objective reality. Different and new to their analysis is, however, what they understand by security. Whilst, for example, the Copenhagen school of security studies claims that security is what is done with it (or better, security is what it does by speech act) (Buzan et al. 1998), Bigo turns this argument on its head and argues that '*what is done with it [how security is practiced] determines security'* (Bigo 2001). To understand what Bigo means by this, it is necessary to dig a little deeper. All of Bigo's (and by extension the Paris school's) works are informed by the same key assumption, namely that there is a merger of – what he calls – 'internal' and 'external' security into a 'field of security', whereby the border between the two ceases to exist. The border between 'internal' and 'external' here is tantamount to the borders of sovereign nation states. This school emphasizes the study of borders and boundaries, especially where discussions of the 'field of security' and the security 'ban-opticon' are concerned (Bigo 2008). This theoretical school studies the functional and de-localized dimensions of state borders as they are practiced and enforced within and beyond the territorial jurisdictions of states.

The Copenhagen School

The Copenhagen School, also known by the introduction of the concept 'Securitization', is the most known Critical approach in Security theories funded by Buzan et al. (2003). The Copenhagen School has represented "a move away from traditional security studies and drew more attention on non-military issues and non-state actors and places" (Lin 2011: 17) in order to develop a constructivist discussion of 'security networks' or 'security apparatus', emphasizing the ability of political authorities to determine what can become a security issue or a threat.

Buzan and his colleagues reflect at traditional regional security complex (RSC) theory, "with its military-political focus, and its firm regionalizing logic" (Buzan 2003: 140), and explain how this RSC is limited to several more or less disconnected systems that exist simultaneously, like international subsystems (Buzan et al. 1998: 6). With the extension of this traditional framework, these critical scholars started to invite others to "elaborate changes in the nature of the security agenda, examining the rise of economic and environmental security, with their new types of threat and new referent objects, and the decline in salience of military-political security issues amongst the great powers" (Buzan 2003: 140). These theorists encourage reflection on the political and ethical implications of the traditional assumption that security means considering the preservation of state sovereignty and territorial integrity.

In their multi sectoral approach to security Buzan, Wæver and De Wilde claimed that security should be upheld split for more detailed analysis. Five security sectors have been proposed – political, economic, military, social, and environmental sectors and elaborated how economic threats become more diverse and therefore the security object would be more complicated.

According to the authors, states in general do not regard economic threats as existential threat (but the 2008 global economic crisis has shown the opposite), and military sector can obviously bring military threats to the state but the Social Dimension of security is also challenging as there is a broad collective identity of certain groups within society with different expectations. In addition, the growing environmental sector covers the security situation of the environment at various levels today, so contrary to (neo)realism, the Copenhagen School questions the uniform nature of the state and the normative definition of threat. Their model contains four conceptual elements: "reference object", "security actor", "existential threat", and "extraordinary measures". According to the Copenhagen school, security actor is the person who turns the matter into a security issue – this actor is mostly the state. And it does so *by declaring something of an existential threat to justify extreme political action*. The most important consequence here is that the whole process is unlikely to be true, but in the best interests of the security agent, which is usually state or political power. This is the process that is extensively used now as 'Securitization' theory.

Subjectivity and the *Securitization* Process

As it was already recognized in the 1960s – security can be approached objectively (real threat) and subjectively (threat perception), and it is by no means certain that these two approaches always coincide. Moreover, a more objective approach only seems attractive at first glance. Indeed, no security theory has created an objective measure of security that can be used to determine with certainty whether a question is "really" a threat or not. Unless, of course, such cases occur most frequently in the military and political spheres when the threat is quite obvious: for example, when enemy tanks cross the border of a country.

Another major difficulty in establishing an objective standard is that security is always about assumptions about the future, about current facts, about what happens if we do not take "security steps" (these threats), and what happens when we do (how do security measures work). With the widening of Security theories there was an increasing versatile approach to security in the 1990s that was strongly correlated with (Neo)constructivist concepts.

After the oil crises of the 1970s in the UN reports of environmental and non-military sectors (such as the Bruntland Commission Report in 1980 or the Palme Committee in 1982) have blurred the boundary between security in military and non-military sectors and introduced a global approach to international security issues. This process is largely interlinked with the concepts of Buzan et al. (1998), on securitization emphasizing the ability of political authorities to determine what can become a security issue or a threat. The theory highlights the somewhat debilitating process that protects against a particular threat or matter question, and which process reflects the interests of the "security actor".

This approach elaborated the diversity of security communities, a concept developed in 1957 by Karl Deutsch et al. that includes both liberal and constructivist elements. Deutsch says that members of the community settle their disputes peacefully and share the same expectations of a peaceful social change. It differentiates between pluralist security communities like the EU and merged security communities like the United States. Adler and Barnett, who put it in a constructivist perspective, argue that security communities have been based on shared values and members with similar identities (1998). Another version of this complex theory is associated with the classic book *Regions and Powers* (Buzan et al. 2003). In this theoretical manifesto, the authors define regions as essential building blocks of international security because, according to the authors, the same members of the regions share a common security concept and are interdependent. Therefore, in case of security issues, states in a region cannot be completely separated. According to Barry Buzan and colleagues, we can talk about the following levels of analysis: international systems (such as today's global international system); international subsystems (regional systems such as ASEAN); units (such as states); actors within the unit (different organizations); and individuals

(Buzan et al. 2006). The securitization process is therefore extremely complex.

Hedley Bull, linked to the English School of International Relations, created the concept of state society (Little 2000). This is a mixed theory which consists realism, and it carries the hallmarks of liberalism, but it also contains critical elements, that justifies its reference here among critical approaches. Bull argues, despite its material reality, the common norms and underlying values that shape international politics. States participate in the work of international organizations and institutions; they influence each other and share certain norms and values. These interactions are manifested through a process of socialization that leads to the society of the states in the international system. The English school accepts the concept of anarchy, but it also emphasise the role of international organizations as well as the role of international laws (Jones 1981). However, anarchy can be mitigated by a sense of community (society) between states, which results in states that are able to accept certain common norms and values.

This securitization theory thus emphasizes that the outcome is shaped by a political process and not necessarily a scientific investigation of the threat. It encompasses the long-term experiences of the collective memory of a given society (think of the Armenian and Jewish Holocaust), the aspirations of opinion-forming strata – intellectuals, economic and political elites (for example, inciting the nationalism of Yugoslav nations in the 1980s and 1990s), as well as the state's geostrategic interests. The problem of defining *security* and *securing a given reference object* is closely linked to the question of the level of analysis. Security theories and securitization can be interpreted on several levels depending on the particular actor what is its purpose.

Criticism

In the ontological sense, the critical tendencies question the traditionally material ontology of theoretical schools such as realism or liberalism. Realism and liberalism accept the concept of objective reality. Realists and liberal thinkers are concerned with details of the material aspects of reality that they can be measured more or less objectively and numerically, e.g., economic variables, military power, territory, population, etc. However, critical approaches deal with its non-material dimension, such as norms, principles, ideas, ideologies, identities, ways of thinking, and cognitive processes. It also means that Critical security thinking does not believe in objective reality, but instead examines the subjective side of understanding reality. "This issue driven widening (of the critical schools and human security theories) eventually triggered its own reaction creating a plea for confinement of security studies to issues centered around the threat or use of force" (Buzan 1997: 6).

"A key argument was that progressive widening endangered the intellectual coherence of security, putting so much into it that it's essential meaning become void. This argument perhaps masked a generally unspoken political concern that allowing non-military issues to achieve security status would have undesirable and counterproductive effects on the entire fabric of social and international relations" (Buzan et al. 1998: 2). According to traditionalists, the concept of security should continue to focus on traditional issues, such as the use or threat of military force while critics believed that the concept of security should be expanded to new non-military nature areas such as the environment, society, and the economy (Collins 2016).

It was also claimed that these critical approaches are Eurocentric; realists accused critical theorists with "intellectual incoherence" and some have criticized the absence of gender roles. In a sense, with the expansions of non-traditionalists after the end of the Cold War together with traditional (military) security interpretations prevailed and has been later extended by new security approaches such as queer theory in IR.

Queer Theory

Theories of feminist security studies and feminist international relations are closely related to constructivism and Marxism. Marxist Feminism, for example, highlights the Marxist roots of feminism. Feminist security thinking draws attention to the current neglect of traditional approaches

research areas such as gender issues, women's rights, vulnerable groups (minorities), children, and the environment. Of course, most of these issues are of increasing importance in times of international conflict. Feminism contributes great importance to security studies, in particular how international conflicts and civil wars affect voulnerable groups considering gender related questions. Warfare is usually tied to men and is traditionally considered a men's business. However, it is women and children who are most vulnerable to conflict and their best interests are never represented in the war when making political decisions. Feminism also seeks to raise awareness on neglecting environmental issues – in general and during armed conflicts too. This is an aspect that traditional approaches completely ignore. In addition, Queer studies represent the ways in which sexualities and gender affect international security, like how some groups become disciplined by traditional sites of power; like how queer identities are subjected to domestic and foreign policy in heteronormative contexts. Ontologically, these theories aim to highlight the position of various marginal groups from a constructivist security approach and show how liminality and visibility is played out in international power relations. At last, epistemologically, this objective covers alternative methodologies to security theories, in particular, to understand intergroup relations behind existing formal bureaucratic entities.

Conclusion

This review aims to provide a brief insight into security theories. In addition to the aforementioned schools, there are many more security theories, but due to the limited framework these could not be discussed here. The richness of every scientific discipline is best demonstrated by its heterogeneity that engenders intellectual debates that further extend our understanding of reality. This also means, of course, that neither theory is "better" or "worse" than the other. These are just theories that have different ontological and epistemological beliefs. We could say that every theory has its own strengths and its weaknesses, and all situations should be handled with the right approach. This heterogeneity also demonstrates the complexity and diversity of societies and demonstrates the multitude of disciplines that offer an understanding of international security issues. Thus, the analyst or scientist must choose carefully the right theory to understand a case in a specific context.

Human security · Guards · Asset protection · Training · Academics · Programming · ASIS International

Definition

Security guards include people employed primarily to perform one or more of the following duties: protection of persons and/or property from harm, theft, and/or unlawful activity; deterrence, observation, detection, and/or reporting unlawful or unauthorized activity; street patrol service; and response to, but not installation or service of, a security system alarm (New York State Department of Licensing 2018).

Introduction

In 2017, 810,000 security guards were employed by industry in the United States with revenue produced topping 25.5 billion (Statista 2018). Variables, such as ample spending and the challenge to reduce liability, justify the importance of training and, where academia can assist, in cultivating personnel who are charged with non-law enforcement responsibilities but who serve as a deterrent and protective layer between theft and physical harm of the public. Program costs will affect the willingness of contract security guard firms to absorb training and development for their staff based on their return on investment.

Academic and training programs have evolved over the years to meet a set of general, minimum standards required by the security industry (e.g., age, residency, high school diploma/GED). Security academic and training programs allow students to reduce risk and liability of "excessive" acts of the profession, as well as provide avenues for students to learn new security methodologies and update their existing knowledge and skills in the field (MBAskool 2018). It should be noted, however, that there is no uniform or national set of standards; instead, individual states determine standards required for certification and employment of security guard forces.

The purpose of this entry is to provide students and professionals with information about types of academic and training programs available for security guards within the United States. The elements that comprise and encompass training programs within regions of our nation that differ in required mandates are reviewed. Additionally, national organizations and academic institutions which possess the resources and capabilities to disseminate course work within this area of subject matter, in traditional and online platforms, are provided.

Security Concerns

Various state-level legislative and regulatory issues and challenges for contract security companies are monitored by the National Association of Security Companies (Amitay 2013). Stakeholders in different regions of industry have increased their financial budgets to cover the use and hiring of security personnel as a means of providing effective protection of their assets and personnel. As the number and types of threats to safety and security have evolved over the past decade, the need to measure and gauge the level of training, knowledge, and capabilities of security guards must increase proportionally. For example, the 2013 *Washington Navy Yard* mass shooting attack raised important issues and challenges related to the adequacy of federal facility security, access control, and personnel background screening. Unfortunately, this active shooter attack was but one of several other recent shootings at federally protected facilities.

Federal agencies and their contract security partners who protect assets and personnel at those facilities must work together to address and develop new efficient and effective strategies to reduce the current risks and threats (Amitay 2013; see Critical infrastructure: Government facilities sector in this encyclopedia). The Department of Homeland Security's (DHS) Federal Protective Service (FPS) is the primary agency responsible for providing law enforcement and related security services for the approximately 9,600 federal facilities under the control and custody of the General Services Administration (GSA). FPS has about 1,200 full-time employees and about 13,500 contract "protective security officers" (PSO's) deployed at thousands of federal facilities (generally Federal Security Level III and IV facilities) of GSA's 9,600 facilities (Duncan 2013). The remainder of the federal buildings and structures are protected by three dozen other federal executive branch agencies.

Not including the military services, there are approximately 35,000 private security officers working for various federal agencies (Amitay 2013). Contract security organizations [see Contract: Security in this encyclopedia] are responsible for the employment, delivery, and training of this capable human resource. At minimum, they must be able to select and sustain properly a higher level of security guard to work within critical infrastructures, as well as other properties deemed hard and soft targets. Potential contract security employees must be taught the appropriate knowledge, skills, and abilities to work competently in this capacity. However, not all of the academic and training programs for security guards are equipped by reputable service providers, up to par based on perceptions of global security service providers, or available in every state.

Assessing Needs: Limiting Liability and Increasing Accountability

It still remains a challenge to find credible information on the number of people working in the contract security industry in the United States (Perry 2016). Nonetheless, it may best advantageous to perform an analysis or reference reported case studies to determine how a synergy of training, education, and technology investment opportunities may offer ideal performance of security guards. Most importantly, applicants should evaluate programs to determine which may offer successful future outcomes during times of escalation, as well as limit employee and employer exposure to liability and lawsuit and, in most extreme circumstances, prevent incarceration of security guard personnel.

In one case, Smith (2018) analyzed conflict escalation resulting in the November 29, 2017, event resulting in an altercation between three contract security guards and residents at Pamoja Men's Homeless Shelter in Bedford Stuyvesant, New York. Captured through surveillance cameras, security guard personnel failed to execute restraint and met resistance with offensive tactics resulting in a guard's termination, a supervisor's demotion, and a civil lawsuit by residents against the City of New York. In addition, the City of New York sued the contract security firm. Litigation is pending and is tied to reports over a 36-month period in which two large New York security firms were accused repeatedly of enabling, and in some cases aggravating, violence inside city-funded shelters.

A second case study can be evaluated through the lens of excessive force in a May 2018 incident in which a security guard was charged with assaulting a teenager accused of shoplifting $850 worth of merchandise from the retailer – Century 21 Department Store in New York. Gstalter (2018) cited witnesses' accounts of security guard staff "choking" the petty thief to restrain her until law enforcement arrived. One security guard was arrested for assault. While the heist was labeled a petit larceny and possession of stolen goods, litigation pending will most likely result in damages awarded due to excessive force by the security staff who are legally responsible under New York State law to only "observe and report" unless defensive measures are appropriate to defend oneself.

A most extreme case involving confrontation between the security guard staff and a hospital

patient resulting in death offers an extreme case review of the questions of risk, liability, excessive force, and, ultimately, training. Alexander (2018) cited the September 29, 2015, MedStar Washington Hospital Center case in which security staff engaged a patient behaving aggressively that resulted in that patient's death. While reports have the patient suffering from a preexisting spinal condition, DC prosecutors alleged that security guard personnel used excessive force to restrain the patient, violently tackling him to the ground and ultimately causing a fatal neck injury. Although the intent of the security guard personnel was to restrain the patient, prosecutors charged two of them with involuntary manslaughter in the death of the 74-year-old patient. As a result, MedStar Washington Hospital spokeswoman called the patient's death a "devastating and transformational moment" for the hospital, stating it will lead to changes involving the hiring and training of public safety personnel at the hospital. Such action to limit future risk and liability has also resulted in changes in the training of caregivers and security officers and the establishment of a new team to respond to "high risk."

Academic and Training Programs

Security guard performance and liability are at the crossroads for the profession in review of performance concerns in modern times (Amitay 2013). Ultimately, an analysis of return on investment should be explored and bolstered for employment organizations which seek to reduce both liability and risk of ill-prepared personnel to meet the demands of the profession and expectations of the public and industry. Nonetheless, critical facility security may not be as simple as posting additional guards. As a practical matter, the effectiveness of guards in countering a terrorist attack depends on the specific types of threats the guards may face, the training they receive, their organization, the conditions of their employment, and background checks (Parfomak and Library of Congress 2004; see Personnel Security: Hiring, Personnel Security: Recruitment, and Personnel Security: Selection in this encyclopedia).

Academia in recent years has studied facets of the expanding market, as well as limiting liability of physical confrontation between security guard personnel and the public. As listed in Table 1, the existence of undergraduate programs currently accredited in the United States whose focal points encompass private security also maintains standards that incorporate security concepts such as physical, information, personnel, as well as other security-related areas. In general, these US-based colleges strive to provide their students with the type of knowledge needed for future positions in security, both in the public and private sectors. In particular, most of the undergraduate programs' curriculum are multifaceted and diverse, as industry standards for the field of security seem to be changing often in post 9/11 times.

In contrast, as seen in Table 2, graduate programs help students to focus on a specialized areas to improve their expertise in the field, gain skills in management, and/or blend

Security Guards: Academic and Training Programs, Table 1 Security undergraduate programs in the United States

College	Undergraduate degrees offered
Bloomsburg University of Penn	BS in Digital Forensics
California University of Penn	BS in Homeland Security
Eastern Kentucky University	AS (Homeland Security or Security Management concentration); BS in Homeland Security
George Washington University	BS in Cybersecurity; BPS in Police and Security Studies
Georgetown University, Walsh School of Foreign Service	BSFS/MA Security Studies

Mercy College	BS in Corporate and Homeland Security
Missouri State University	BA in Global Studies
SUNY Farmingdale	BS in Security Systems
University of Maryland	BS in Computer Networks and Cybersecurity
Virginia Commonwealth University	BA in Homeland Security and Emergency Preparedness

Security Guards: Academic and Training Programs, Table 2 Security graduate programs in the United States

College	Graduate degrees offered
Anna Maria College	MA in Security Management
Auburn University at Montgomery	MS in Justice and Public Safety
California University of Penn	MS in Homeland Security
	MS in Cybersecurity
Eastern Kentucky University	MS in Safety, Security, and Emergency Management
Georgetown University	MA in Security Studies
	MA/Ph.D. in Security Studies/Government
George Washington University	MS in Security and Safety Leadership
John Jay College	MS in Protection Management
	MS in Security Management
	MPA-MS in Public Policy and Protection Management
John Madison University	MS in Information Security
Long Island University at Riverhead, Homeland Security Management Institute	MS in Homeland Security Management
Missouri State University	MS in Defense and Strategic Studies; MS in Cybersecurity; MPS in Homeland Security; MS in National Security
National Defense University, The College of International Security Affairs	MA in Strategic Security Studies
New Jersey City University, College of Professional Studies	MS in Professional Security Studies
Southwestern College	MS in Security Management
University College	MAS in Security Management
	MAS in Organizational Security
University of Denver	MA in Homeland Security
	MA in Security Management
	MAS in Security Management, Information Security
University of Detroit Mercy	MS in Security Administration
University of Houston Downtown	MA of Security Management for Executives
University of Maryland	MS in Counter Terrorism and Security
	MS in Cybersecurity
University of Nevada, Las Vegas	MS in Business Continuity, Security, and Risk Management
Virginia Commonwealth University	MA in Homeland security and Emergency Preparedness
Webster University	MA in Business and Organizational Security Management

knowledge and skills from different areas (e.g., Government/Public Management and Security). One way graduate programs do this is by adding a leadership and business continuity component, enforcing public and private sector comparisons and contrasts. These comparisons and contrasts within the curriculum often culminate to an understanding of how an organization permits and sustains growth. Students may learn that without the business side of security, a firm that supplies these services may not be able to benefit and reap rewards.

Another way to improve their expertise in this field is incorporating a major research component into a graduate program for students to delve into a particular phenomenon or problem. Most of these perceived problems pertain to the current state of security in today's society or at least one major area of it. The end result and objective, by in large, will be to create the skill set to defend a thesis or dissertation relevant to their research. Research is data-driven, and security is one major industry which has adopted many data-oriented deliverables within an organization.

Training programs have a different focus than do academia. Agencies and organizations conduct evaluations and assessments on risk, and an abundance of this risk exists in the area of human error. Unbeknownst to many people who work outside the field of security or those who are removed from any scenario in which security is a necessity, programs exist which mission is to spread the message that they are here to educate and train within all levels of the industry, for instance, the National Association of Security.

Companies (NASCO) work closely with state associations, business groups, contractor organizations, and security organizations on mutual issues of concern. NASCO, in particular, articulated that "their biggest highlight" was the completion of a joint project between John Jay College of Criminal Justice and themselves to create an electronic database of state security licensing laws, regulations, codes, and policies governing the licensure of armed and unarmed security officers.

The database will be continually monitored and updated by John Jay with input from NASCO members (Amitay 2013). As the national leader and voice of the contract security industry, NASCO constantly interacts with Congress, federal agencies, state legislators, regulators, the courts, and the media on a variety of industry-related issues. NASCO continued to work with Senator Pat Toomey of Pennsylvania on a bill that will provide security officer employers with *on-demand* nonstate-based access to FBI checks on officers and applicants (Amitay 2013). This working relationship has stayed consistent on the federal level.

At the state level, there continues to be numerous legislative and regulatory issues and challenges for contract security companies in which NASCO was involved, working directly with legislators, regulators, lobbyists, and state associations. In Maryland, a NASCO supported bill to synch up renewals of firearm permits with armed guard licenses was enacted into law. In Connecticut, NASCO, with the assistance of local legislative counsel, worked to find a legislative or policy solution to the current massive delays in officer licensing related to the FBI check process for security officers. In Minnesota, NASCO worked with the state regulatory agency officials, local NASCO company personnel, and the Minnesota state association to stop at the last minute a bill that would have mandated a single uniform and vehicle color for private security. In the state of Washington, NASCO established a working relationship between NASCO members in Washington and the State regulatory agency to address delays in armed officer licensing (Amitay 2013).

Founded in 1955, ASIS International has promoted itself as a global community of security practitioners, each of whom has a role in the protection of assets – people, property, and/or information [see ASIS in this encyclopedia]. ASIS states "No other organization possesses the vast array of knowledge, expertise, and experience" (p. 1). Furthermore, ASIS "offers a range of education programs, publications, and events to help you thrive professionally, whether you're a young professional or an industry veteran" (ASIS 2018, p. 1). The evolution of ASIS on guard training is very evident from an organizational standpoint. Within their educational programming, ASIS provides course curriculum for security practitioners. Training is delivered through multiple means, including online, face-to-face classes, and live webinars. ASIS courses include "Strategy & Tactics in Crisis Management: From Prevention to Recovery" providing a hands-on workshop to teach security personnel how to "analyze methods to manage and control communication, examine components of a comprehensive workplace violence program, strengthen strategies for protecting brand and reputation, examine crisis recovery and consequence management, and discuss how cybersecurity issues affect crisis management" (ASIS 2018, p. 2).

Conclusion

Expectations for training are often correlated with mandates. In the state of New York, security guard

training requirements, Section 89-G of Article 7A of the general business law, requires all persons engaged in security guard activities to be registered with the New York Department of State (DOS) and to complete all trainings (unless exempt) at schools approved by the Division of Criminal Justice Services (NYS Department of Licensing 2018).

In the very place where the most prolific attack on American soil occurred, in New York, the following training courses are required for security personnel, where security guard (unarmed) initial training requirements are an 8-hour pre--assignment training – a general introductory course – and a 16-hour on-the-job training (OJT), a course relevant to the duties of guards, requirements of the work site, and the needs of the employer. This training must be completed within 90 days of employment as a security guard (NYS Department of Licensing 2018). Annually, training requirements are an 8-h annual in-service training, completed each year. In New York registration is issued for 2 years; therefore, security personnel must complete two 8-h annual in-service training courses within their registration effective and expiration dates to be eligible for renewal (NYS Department of Licensing 2018). One may wonder if this is enough. Regardless, despite one's level of education, based on the ample opportunity in our nation to advance, time will tell if these requirements fit the bill within the training and development genre necessary to uphold industry standards and protect life and property.

Definition

A security guard is a private citizen employed by individuals and organizations to protect the life of these persons: their staff, their clients, and their property.

Introduction

Although there is a general decline in crime in developed countries in Europe and North America, there has been an increase in the number of private security providers because of the reassurance paradox. This paradox reveals that there has been an increase in perceived victimization as the general risks of crime has declined. The anxiety and fear emanating from this paradox suggests that the rise in private security may have to do more with generalized feelings of societal insecurity rather than the crime rate. The opposite is the case in Latin America and the Caribbean where the discourse of insecurity is more reality than perception because the region has the highest rates of homicides and other violent crimes in the world. Security in developed and developing countries has been dubbed a societal priority hence the need for greater private security (van Steden and de Waard 2013).

The number of security guards tends to be three times the number of law enforcement officers and they provide a critical and crucial security support to law enforcement agencies especially since the 9/11 terrorists attack against the United States. This is evident in the United Kingdom where the police have co-opted private security and have held joint drills with them, among other security and emergency institutions, to better respond to terrorists attacks, and other national emergencies. Both the police and private security believe that such partnerships are beneficial but each group believe that the other could do more to enhance the partnership. This public-private security partnership, which experiences tension sometimes over working relationship and accountability, has nevertheless expanded the society's security architecture. The partnership has also reshaped the structure and function of modern policing. Private security companies have also penetrated new markets overseas and are now part of a global security industry with multinational companies (Cohen 2004; Nalla and Critchlow 2017; Lopes 2018; Shearing and Stenning 1983; van Steden and de Waard 2013).

The jobs held by security guards are generally considered low paying and hence low status jobs. The status of these jobs depending on the country is further exacerbated by societal cleavages based on race, ethnicity, skin color, gender, level of education, and social class. Despite these pejorative contexts, security guards derive their power and authority from several sources. Authority as used here denotes the right to give instructions and exercise control, and power means the influence or capacity to enforce compliance. Employers invest power and authority in the security guards that they employ to secure their property and government regulation of the security industry all of which enhances the legitimacy of security guards. Their authority and power also comes to a lesser extent from the important roles and functions in which they perform comparable tasks to the police services, the security partnerships built with law enforcement agencies, and the perceived positive impact of their work on crime reduction and enhanced societal security (Nalla and Critchlow 2017; Schnabolk 1982; Shearing and Stenning 1983).

Types of Security Guards, Their Roles, and Functions

There are several types of private security personnel. Some of these are residential guards, private guards, patrol guards, business guards, stationary guards, plainclothes guard, uniformed guards, contract guards hired through a private company, proprietary guards that are hired directly, unarmed guards, and armed guards. These guards work in a range of domains such as federal government ministries, agencies and departments, schools, universities, public housing projects, private homes including gated communities, non-gated communities, and state and city agencies, private corporations including financial institutions, malls, and not-for-profit organizations. They also work in religious institutions, entertainment, recreational and sporting events, nuclear facilities, disaster zones, airports, seaports, and on public transportation, airplanes, and commercial ships to prevent piracy on the high seas (Nalla and Critchlow 2017; Petrig 2013; Shearing and Stenning 1983).

Security guards' duties are wide ranging and they have the authority and power (similar to that held by private citizens) to respond to illegal activities at the workplace. The major duties depending on the type of organization are providing information to clients about procedures, and the services and products offered; controlling traffic flow in the workplace by directing motorists; sounding the alarms when necessary to get help; effective use and monitoring of surveillance technology and equipment; periodically inspecting equipment, points of access, buildings, and allowing entry to clients; searching departing clients and staff; patrolling the facility thereby securing staff, clients, and the property; stopping trespassers; and informing those who break the rules of organizational policies and procedures (Lopes 2018; Schnabolk 1982; Shearing and Stenning 1983).

Other duties include documenting and reporting irregularities discovered; providing forensic services; preventing loss and damage to facility; environmental maintenance through the setting and controlling of equipment and buildings including preventative maintenance; assessing new equipment and contacting repair services; following the requirements of the law in support of the reputation and stability of the organization; participating as a cohesive team member to produce outputs; investigations; writing reports of observations, evaluations, and breaches including the recording of witness statements (van Steden and de Waard 2013; Lopes 2018; Schnabolk 1982; Shearing and Stenning 1983).

Public and private organizations invest their security guards with the authority and power to carry out the foregoing roles and functions on their private property within the rule of law (Petrig 2013; Schnabolk 1982). For example, increasing theft in the workplace has influenced some corporations to ask security guards to search customers and staff leaving the premises. This request which is within the rights corporations have to protect their property have to be balanced against the rights of individuals to privacy. Some countries, e.g., Brazil legislate and regulate the powers of search that security guards have at the workplace (Lopes 2018). There are several advantages and disadvantages that have developed as security guards leverage their authority and power in the workplace on behalf of their employers in the service of profits (Schnabolk 1982; Shearing and Stenning 1983; van Steden and de Waard 2013).

Advantages and Disadvantages of Security Guard Work

There are several advantages. The presence of private security in partnership with the police increases societal capacity to control insecurity particularly crimes, terrorism, and other security risks. The pluralization of policing facilitates coordinated synergy between the police and security guards that enhances the security network infrastructure, as well as improved information gathering and sharing. There is also the civiliani-

zation of policing with security guards taking over soft policing roles such as directing traffic, taking emergency calls, serving warrants, and escorting prisoners thereby freeing the police to engage in hard policing and traditional forms of policing. The private security presence also provides competition to the police services that tend to increase performance evident in reduced response time to calls from citizens and increases in the quality of service to the public. Private security services thrive in the market that has limited governments and as such are more adaptive to the changing crime ecology, the new types of crime, and the use of new technology compared to the police. Moreover, private security vendors offer client-oriented services compared to the police where security guards are expected to produce surplus value (Cohen 2004; van Steden and de Waard 2013; Lopes 2018; Nalla and Critchlow 2017; Shearing and Stenning 1983).

Other advantages are that security guards are seen as major contributors to the crime decline. These guards are considered the first line of defense. Therefore, these private security personnel as such are viewed as guardians in the community that produces safety with very little civil liberty problems. Moreover, they have turned gated communities into zones of risk suppression. Security guards' uniformed presence also increases people's feelings of safety especially in unsafe contexts. It is also important to note that private security service users tend to rate the interpersonal competencies of the guards highly compared to the guards' rating of themselves. Security guards have also been hailed as heroes for their help in emergencies like floods and fires and so on. These advantages influence many members of the public to view security guards positively with increased confidence based on increased trust and satisfaction with them. However, Whites held more negative views about security guards than Blacks. Also, lower income individuals compared to middle class persons prefer security guards compared to the police (Nalla and Critchlow 2017; Schnabolk 1982).

The disadvantages associated with the work of security guards undermine their authority and power. Competition in crime and security can undermine the public-private security partnership reducing the effectiveness of the overarching security network. Blurred operational lines between private and public security sometimes occur leading to public governance through private security. This occurrence is a threat to democracy. Moreover, some private security personnel are associated with paramilitary violence and the accountability system for the private security industry is inadequate (van Steden and de Waard 2013).

Countries are moving towards the creation of a greater disciplinary society with greater private security to protect property rights that have led to threats to individual liberties. The police, for example, have arrested and charged some security guards for rape, assaulting customers, or the use of excessive force, theft, drug use, facilitating drug transactions, false imprisonment, and shooting people in the back. Other security guards have been accused of attacking psychiatric patients, discriminating against minorities leading to lawsuits, and failing to respond to reported crimes and so on. As such, some people hold negative views of security guards because some have not been compliant with the stated demands of private security vendors (van Steden and de Waard 2013).

Some of the disadvantages of private security that have been identified above may be addressed in several ways. These are that security guards should receive better education and training, they should have better amenities at work, also better work schedules, receive livable wages, health insurance and pension, and be provided with ongoing corrective feedback about their performance (Cohen 2004; Hemmens and Klein 2018). Dealing with the foregoing should increase the security guards' job satisfaction and reduce the high rate of job turnover. Governments tend to respond to these problems, the crime concern and the respect for civil liberties by regulating the private security industry (Lopes 2018).

Regulating Security Guards

There are generally regulations governing security guards that vary based on country with developed countries having more regulations than developing

countries. These regulations are of critical importance because private security firms perform comparable functions to the police. In the case of the United States, approximately 90% of the states have some regulations governing private security in the absence of federal guidelines. These requirements for hiring security guards are designed to protect the public. The push to professionalize the private security industry and make it adaptable to challenges has been unremarkable in some countries. However, the overall push has made the industry more accountable which has given it more legitimacy with citizens (Hemmens and Klein 2018; Lopes 2018; Nalla and Critchlow 2017).

Most states in the United States have licensing requirements for security guards but there are none in Missouri, Mississippi, South Dakota, Colorado, and Idaho. Some 84% of the states require a criminal record check for security guard applicants with 64% of the states requiring proof of citizenship or permanent residency status, 45% requiring training for unarmed guards, and 12% requiring training for armed guards. For the latter category of guards, 84% of the states have a minimum age requirement. The states that did not have specific armed training requirements for security guards relied on the firearm licensing laws of the state. Although training of security guards is largely neglected in the country, the states of California and New York have made training and oversight mandatory. Only 29% of states have a minimum education requirement for guards with only 10% requiring applicants to sit a written examination (Hemmens and Klein 2018; Nalla and Critchlow 2017).

Private Maritime Security: Security guards working on board ships for private maritime security companies to counter piracy on the high seas are a challenge to the notion of the navy and the coastguard having responsibility for maritime security. Naval presence is important but it is not necessarily a deterrent to piracy. Shipping companies have two choices. The first is the use of private maritime security companies and the second is the use of vessel protection detachments that are small teams of security personnel on board the ship acting in their capacity as state officials serving as police or military personnel. The latter have the right to use force as agents of the state. Although companies have a preference for state officials, there is limited resources so some civilian companies use private security guards. Therefore, some countries have started to review their legislations to allow the use of private security guards on commercial ships (Hemmens and Klein 2018; Petrig 2013; Schnabolk 1982).

Some of the rules governing private maritime security states that these guards should always have access to maritime legal advice because the position of the armed guards are not precise under international law and the domestic laws of countries. The laws dealing with carrying and using guns on board ships along with other security equipment are sophisticated. The laws of the flag State govern guns and armed guards on ships traversing the high seas. The country to which the ship is registered is the obligated state under international law to prescribe and enforce rules. Maritime security guards may also be obliged to follow the laws of the country in which the company is incorporated. Therefore, a commercial ship using armed private security personnel and going through a third state's territorial waters, or using a foreign state as a port of call, is expected to comply with the laws on the use of firearms in the coastal and port states that may differ from the gun laws of the flag State. The maritime security guards derived their authority and power at sea from their employers and applicable laws similar to their counterparts working on land (Hemmens and Klein 2018; Petrig 2013; Schnabolk 1982).

Conclusion

There has been the globalization of private security companies employed in organizations ranging from schools to public transport and companies whose ships traverse the high seas and companies in response to the perceived rise in crime, terrorism, and other security risks. Security guards and the new technology they bring in client-oriented services in the market have led to fruitful partnerships with law enforcement agencies despite the occasional competition and tensions. Private security companies are now an important part of the security structure in the modern world. Their

authority and power are largely derived from their contracts to protect people and their private properties and the state regulations governing private security companies that enhances and legitimizes them. They also emanate from the important security roles and functions they perform in society, their security partnerships with the police, their perceived role in the crime decline, and enhanced security. Therefore, the post 9/11world now has plural policing comprising strategic public-private security partnerships buttressed by the support of citizens that have changed the nature of security in the modern state system.

Definition

Security management is the administration of a program that protects or reduces assets from loss.

Introduction

Security management is the administration of a program that protects or reduces assets from loss. In an earlier era, the definition of security frequently used was "private people protecting

private property." That early characterization was in decline by the turn of the twenty-first century and became obsolete following the terrorist attacks of 9/11. Those attacks affirmed the role of security as a private resource but one that also suggested a duty to reasonably aid the public within its limited sphere of influence (IACP and COPS 2004; McCrie 2016).

A Discipline in Development

Security in the context of this discussion means secure, safe, and free from care. It embodies the concept of safety and freedom from worry and danger. The word *management* comes from Middle Age derivatives of the French *ménagerie* (housekeeping, including animal care, especially horses) and the Italian *maneggiare* (to handle, especially tools or a horse). This artisanal and barnyard word origin belies a serious responsibility not so discernible in contemporary use: administering property and taking care of horses – the most valuable and useful domestic animal in earlier centuries – required knowledge, commitment, and reliability.

Without management, progress would be stuck; the fruits of civilization would be blocked from flourishing. Humankind has achieved grand objectives first by planning and then managing the plan to reach the goals that were decided upon. Through management, past civilizations created the precisely engineered pyramids, the Great Wall of China as well as city walls throughout the developed world, vital aqueducts and road systems, military fortifications and structures, and inventions that could make products in quantity and for less cost than low-production handcrafted methods of the past. Management's objectives do not relate exclusively to the concerns of structures or manufactured goods. Effective management also encompasses functional strategies for achieving countless other physical and operational achievements that embody the human spirit in striving for a safer, richer, better life. None of these achievements could have occurred spontaneously out of chaos and disorganization. People alone turned dreams into systematic concepts and then organized the resources to achieve their ultimate objectives.

Yet general management, as an academic discipline and subject of critical analysis, is just about a century old. The Wharton School began in 1881 with an undergraduate focus. The emergence of graduate schools of business administration created a further emphasis on identifying what makes organizations succeed or fail (Cruikshank 1987). The contributions of classical management provided a framework for thinking about management with the writings of Henri Fayol. Classical management exponents concentrated on production and predictability: Frederick Winslow Taylor, Frank and Lilian Gilbreth, and Henry L. Gantt. Early on, the case history method became a core strategy of examining strengths and weaknesses of actual organizations, probing their strengths and weaknesses, and challenging student analysts to find a productive way ahead (Heath 1998; Cummings 2017). Future executives and senior managers learned to set the strategy and amass the resources to meet the expectations of capital providers, institutional visionaries, and government functionaries. But what about security management?

We argue that security is the first necessity of any organization (McCrie 2006). Without protection of assets, work cannot be accomplished with certainty, plans cannot be assured, and creativity may be squandered. Not every workplace requires a security manager or an articulated program. A great many workplaces have common sense protective measures as part of their organizational DNA, and conventional security responsibilities are dispersed within them widely. Similar to early management practitioners, contemporary security managers concentrate on collecting and assessing activities related to their responsibilities to improve plans and programs. All organization have the challenge and duty to protect assets from loss, and as organizations expand in size and complexity, the utility of having timely practices and knowledgeable managers to mitigate losses increases, especially for cybersecurity, protection of intellectual property, and executive protection.

Security management became recognized as a distinctive discipline, gradually emerging as a topic for research and teaching during the Cold War era

and drawing from teaching and research in graduate management education. A starting point was the organization in 1955 of the American Society for Industrial Security, now ASIS International (McCrie 2005). A handful of security directors, most with government-issued security clearances, first met in Los Angeles, to discuss challenges in protecting the critical national activities they performed for the federal government. Quickly, security directors in other industrial and commercial sectors, and those with related responsibilities, sought this forum to associate with practitioners to share views and obtain information vital to the conductance of their individual activities. They wanted in. The new organization began to grow. Currently, ASIS International claims 35,000 members in over 240 chapters around the world. However, as managerial interests expanded and became more specialized, literally scores of trade and professional organizations could be identified that serve various loss mitigation and recovery activities (Security Letter 2017).

The process of security management continues to evolve, but two fundamentally different tasks are apparent. Management skills are needed to administer ongoing programs or endeavors. That is, the manager continues to direct with appropriate change what has already been ongoing. But a distinctive set of management skills is required to launch new projects or programs. The sequence of this planning process involves sequential and interlocking progression that is applicable to security planning as well as general management endeavors:

Setting the Goal

Leaders decide what existing program needs to be administered or what new initiative must be set for the organization to move forward. Someone is appointed to be in charge.

Gathering the Information and Analyzing it

The new venture to be managed well needs to be planned using all relevant data sets and experiences. In a security program, such information must be considered like crime trends, available police and emergency resources, past relevant incidents, physical location of the entity for which the plan is being created, personnel required, technical skills needed, and numerous other factors. The security planner or planning team then meticulously envisions the end result and identifies the resources needed and timeline requisite for achieving the goal. This flows into the next step.

Organizing the Plan

The manager looks toward the ultimate goal and allocates funds and human resources toward fulfilling the plan. Depending on the complexity of the objective, the time required can be as little as a few hours to many months of concerted activity by a team. The process of planning brings together the totality of the organization's resources, including personnel skills, technology, industry trends, laws and regulations, and available financing to make the plan achieve its objectives. The plan becomes ready to launch, though remains flexible to changing circumstances.

Deputizing Someone to Manage the Plan Once the Plan Is at an Advanced State

The initial planner might be responsible for managing the resultant new plan that is in place. But in many cases, particularly in complex organizations, a member of the planning team is selected to take personal responsibility for managing what has been created. The plan has moved from the realization of a need to the formation of a strategy to operate and manage what has become the organized, financed, staffed, and supported operation that will continue and hopefully bring desired results. This phase being completed, the senior manager normally allows the subordinate to assume the authority linked to responsibility for working toward achieving the agreed-to programmed objectives.

Supervising the New Manager

In this scenario the initial head of planning supports the subordinate in achieving the established goals of the process.

Constant Program Revision and Enhancements

A program once created is likely to undergo nuanced changes with experience of the ongoing plan. This is a normal expectation in security management due to incessant change of circumstances.

This process with analyze-organize-deputize-supervise at its core is the mantra for high-performing security managers as well as managers with different organizational responsibilities.

Through this process, security management seeks to provide relevance to organizations by reducing constantly evolving risks, responding to emergencies and disasters, meeting legal requirements, working with other managerial entities, and protecting organizational capital, resources, and reputation.

Conclusion

Risk occurs in all organizations and constantly evolves. Its reduction is a function of management that links controls to the identified risk. Security management can be practiced in small organizations by a single individual working on an ad hoc basis to a complex program employing thousands and with a budget in the nine digits. The manager in charge begins with collecting relevant information to create the operational plan. Then, the steps needed are organized for action. Someone is placed in charge to manage the new plan, and the senior manager supervises the ongoing fulfillment. Yet, security management is a dynamic activity, and new issues arise regularly, requiring the management protocols to be adjusted.

Definition

Academics and policymakers designate politically violent attacks perpetrated within the US territory, by groups, which are mostly based in the United States as (American) domestic errorism. The American Federal Bureau of Investigation (n.d.) defines domestic terrorism as acts "perpetrated by individuals and/or groups inspired by or associated with primarily U.S.-based movements that espouse extremist ideologies of a political, religious, social, racial, or environmental nature."

Introduction

However, such a definition can also lead to the inclusion of groups which while are based in the United States operate in a context of a foreign conflict. For example, when presumably Palestinian militants assassinated Yosef Alon, the military attaché to the Israel Embassy in DC in 1973, it was clear to the FBI that the assassination was in the context of the Israeli Palestinian conflict (TOI Staff 2017). Hence, it is conceptually useful to add that local groups in US territory do not just perpetrate domestic terrorism, but these groups may also perpetrate attacks in the context of local political or social conflicts.

Probably the first American group which engaged in a continuous campaign of what can be defined as domestic terrorism emerged in 1865 when former officers in the Confederate Army formed the Ku Klux Klan in Pulaski, Tennessee (McVeigh 2009; McVeigh et al. 2004). While the first Klan lasted for only a brief period, American political, religious, and Nationalist groups continue to engage in campaigns of terrorism to promote their ideological objectives. The main reasons for the emergence of these groups, their ideological foundations, and their operational characteristics will be the main focus of the discussion in the following sections. After discussing violent manifestations from the American Far Right, including racialist, anti-federalist, and fundamentalist groups, we will

address the violentgroups which originated from the American Far Left, to include also anarchists and environmentalist extremists. Subsequently, we will examine the jihadist movement in the United States, as well as analyze domestic ethnic and ethnonationality violent movements. We will conclude with a comparative overview of the main features of domestic terrorism in the United States.

American Far Right

The American Far Right is highly diverse and fragmented. It is characterized by significant ideological diversity (as different groups emerged from distinct cultural traditions), organizational instability (frequent merges and splits), as well as various operational methods, as different groups prefer to use different tactics against different types of targets. Nonetheless, two dominant ideological tendencies seem to be shared by most American Far Right groups. The first is the aspiration that all residents or citizens of the polity/community will share the same ethnic, religious, and national characteristics. This desire for internal homogenization led many American Far Right groups to emphasize that contemporary social, economic, and political crises are resulting from the inability of modern societies to implement this principle. For example, in 2016, the Californian "Loyal White Knights" was involved in a series of violent protests which linked immigration, terrorism, and street crime (Queally 2016). The second ideological element which is shared by most far-right groups in the United States is opposition to foreign influence and the rejection of non-native cultural, religious, and normative practices. Thus, they oppose the assimilation of non-American holidays/costumes, social behaviors, art, linguistic phrases, musical themes, etc. They consider foreign influence as a threat to the ability to maintain what they consider American heritage, a way of life, and exceptionalism (Rice 1972). In this context, many of them also exhibit practices of xenophobia and racism and promote various *exclusionary* policies.

Despite the complex nature of the American Far Right, scholars have divided it into three major streams, which have unique ideological origins and specific operational and organizational characteristics (Durham 2000, 2003; Perliger 2012). The first is the racialist stream, which asserts that Americans of European ancestry, particularly those from Northern Europe, are superior to people from other parts of the world. Adherents believe that "white" people should maintain control over social, economic, and political domains in the United States, and people from other ethnicities and racial groups should not integrate with white people (Barkun 1997; Perliger 2012). This desire results in ideological beliefs which correspond to nativism, racism, and xenophobia.

Three types of movements dominate the racialist stream: the Ku Klux Klan, Nationalist Socialist Movements, and the American Skinheads (Perliger 2012). The Ku Klux Klan has a long history, disbanding and rebranding itself numerous times throughout the twentieth century (McVeigh 2009; Perliger 2012). Although each emergence of the Klan was characterized by a new set of tactics, membership criteria, and organizational structure (McVeigh 2009), its ideology maintained its focus on preserving racial segregation and opposition to legislation and policies which aimed to ensure racial equality in various spheres of society. Local Klan chapters mainly emerged in locations where white protestants were the overwhelming majority and maintained some level of independence (McVeigh 2009; McVeigh et al. 2004), even though the movement was governed until the late 1940s by a national hierarchal structure led by the Grand Wizard. The Ku Klux Klan saw its height in the early twentieth century. However, after significant attention from law enforcement and legislation, Klan organizations rapidly declined in the late 1960s and early 1970s century. This crisis opened the door for the rise of new and young leadership, which in the 1970s and 1980s, adopted the white supremacy rhetoric. David Duke, at that time one of the emerging leaders of the KKK, described this transition as a move from the "cow pastures" to the "hotel meeting rooms" (Wade 1987, p. 368).

This phrase reflected the transition from a language focusing on degrading other ethnic or religious groups to a protectionist language focusing on the need to protect the civil rights and heritage of the white people while also asserting that segregation and exclusionist policies will also benefit non-white groups. The group's reforms did lead to some rise in the Klan's membership, the resurgence was minimal, and today most KKK chapters throughout the United States are small and inconsequential, commonly appearing in news media for their attempts to recruit new members (for example, Craig 2018; Hafner 2018; Nero 2018).

The Nationalist Socialist Movement first emerged in the 1930s and 1940s in response to the rise of Nazism in Germany. However, the movement remained small and failed to gain traction despite the charismatic leadership of George Rockwell, the formal leader of the American Nazi Party in the 1950s and 1960s. However, in the second half of the 1970s, the National Socialist Movement finally gained significant ground, via the National Alliance, the most violent and well-organized neo-Nazi organization in the United States (Southern Poverty Law Center n.d.). The National Alliance was responsible for the expansion of Resistance Records, a Neo-Nazi music company which, at its height, had an annual income of over $1,000,000 (Southern Poverty Law Center n.d.), as well as able to mobilize support from various facets of American society effectively. However, National Socialism began to decline in the 1980s due to the aging of its membership and the growing challenge to recruit a new generation of activists. One of the reasons for this challenge was the emergence of a new, youth-centered subculture, which its members where known as Skinheads.

The Skinhead Movement originated in the 1970s in the United Kingdom as a movement which rejected the free-thinking hippie movement, attracting white, working-class youth (Pollard 2016; Southern Poverty Law Center 2012). While racism and neo-Nazi ideology were not always synonymous with Skinheads, racist organizations dominate the American Skinhead subculture which started to proliferate in the early 1980s. American skinheads groups relied on economic and social anxiety to mobilize young, uneducated, white Americans (Perliger 2012) who were attracted to Skinheads propaganda which blamed globalization and increasing immigration for the difficulties of working-class white Americans (Pollard 2016; Southern Poverty Law Center 2012). Initially, the skinhead movement lacked any central coordination, but during the 1990s, most Skinhead organizations eventually became affiliates of the Hammerskin Nation, the largest and most well-organized Skinhead organization in the United States (Anti-Defamation League 2005a, b; Perliger 2012). The organization continued to evolve – developing a national headquarters and international affiliations – until the late 1990s and early 2000s, when it began to fracture, resulting in the creation of independent Outlaw Hammerskins groups (Anti-Defamation League 2005b). Currently, the Hammerskin Nation maintains a popular online community and has international affiliates. Collectively, National Socialist and Skinhead organizations are known as the White Power Movement, along with others in the racialist stream (Blee 2002; Dobratz and Shanks-Meile 1997; Simi and Futrell 2010).

The second stream of the American Far Right is the anti-federalist movement, which is a new phenomenon compared to the long history of racism in the United States. The anti-federalist movement emerged in the 1970s "based on the idea that there is an urgent need to undermine the influence, legitimacy, and practical sovereignty of the federal government and its proxy organizations" (Perliger 2012, p. 28). Anti-federalists embrace three central views. The first is that there is a concerted effort by the US Government to strip Americans of their rights (Belew 2018). The second implicates a larger shadow government poised to overthrow the US Government and institute a "New World Order" under the control of the United Nations (Pitcavage 2001). Lastly, some adherents promote anti-Semitic conspiracies of a Zionist Occupied Government, known as the ZOG, in which a worldwide Jewish conspiracy controls the US Government (Dobratz and Shanks-Meile 1997;

Durham 2003; Simi and Futrell 2010). While these beliefs do not apply to all anti-federalist organizations, all of the organizations promote the idea that the US Government is already corrupt or highly influenced by foreign actors who facilitate its corruptive nature (Perliger 2012).

The anti-federalist stream includes a variety of tax protest, anti-government, and militia groups. Tax protesters have never gained significant attention in the United States, and most shun violent acts against the US Government. One of the few anti-taxation organizations which garnered substantial support was the Posse Comitatus. The Posse Comitatus was active from the early 1970s through the 1980s. It combined anti-tax ideas with mild racialist sentiments and rationalized the illegality of federal taxes by asserting that the only legitimate form of governance in the United States existed at the county level. Additionally, the Posse Comitatus capitalized on the 1980s farm crisis and the insecurities of poor, rural, white Americans who felt a decline in their social status to spread fears of an overreaching government and a collapsing rural economy (Audsley 1985; Levitas 2002). In this context, the Posse Comitatus actively promoted conspiracy theories regarding paper money. They offered fraudulent paper checks to farmers to repay their loans and argued that since the bank paid the farmer with a check, the farmer could repay the bank with any paper check, regardless of its validity. As the Posse Comitatus' financial tactics failed, they resorted to violence to defend family farms and to counter attempts by the IRS to enforce federal tax laws. The most notable violent incidents occurred in 1983 when Gordon Kahl, a member of the Posse Comitatus, killed two federal marshals who attempted to arrest Kahl for tax evasion (Levitas 2002). While the Posse Comitatus dramatically declined in the mid-1980s, the organization laid the groundwork for future tax protest and anti-government organizations, including the Sovereign Citizen Movement.

The Sovereign Citizen Movement, also known as *Freeman on the Land*, and similar terms, expanded rapidly after the housing collapse and the great recession which the United States experienced in 2008. Sovereign citizens are "anti-government extremists who believe that even though they physically reside in [the United States], they are separate or 'sovereign' from the United States." Ideological adherents often refuse to pay taxes and to recognize or cooperate with public officials. Another common tactic is the filing of fraudulent tax returns to recoup the money they believe the US Government is holding under their name (a belief which is an outcome of a standard conspiracy theory among sovereigns, known as redemption theory) (Berger 2016b). Beyond financial-based crimes, sovereigns account for more than 40% of financial crime associated with the American Far Right (Sullivan et al. 2015); some sovereigns also engage in violent practices, mainly against proxies or representatives of the federal government. Between 2000 and 2016, sovereign citizens were responsible for the deaths of 18 law enforcement officers and 9 civilians and for the injury of 17 law enforcement and 9 civilians (MacNab 2017). While sovereigns are currently more popular than other anti-federalist movements, they maintain a much more decentralized structure and seem to be less coordinated, hence mainly operating independently.

In the early 1990s, militia organizations existed in all 50 states. This trend reflected the growing distrust of the United States federal government as a result of declines in family-run farms and declines in industrial jobs for service-based and high-tech oriented jobs (van Dyke and Soule 2002). Most of the militias engaged in military training and produced propaganda material which promoted various NWO narratives. However, some militia members occasionally also plotted violent operations, as a protest against what they perceived as the tendency of the federal government to promote intrusive policies which are contradicting their constitutional rights. The most known such incident was the Oklahoma City Bombing on April 19, 1995, in which the explosion of a Ryder truck bomb outside the Alfred P. Murrah Federal Building in Oklahoma City caused the death of 168 people and the injury of close to 700, and was the second largest terrorist attack in the United States. It was

perpetrated by Timothy McVeigh, who was later linked to a variety of anti-federalist organizations and adopted extreme anti-federal convictions (Belew 2018).

Following the attack in Oklahoma, the federal government and state legislatures acted quickly to limit the organized activities of anti-federalist organizations. While these actions reduced the capabilities of the organizations to conduct training and mobilize support, the legislation did not alleviate the grievances that led to the expansion of the militia movement and other anti-federalist groups (Vertigans 2007). Thus, the militia movement experienced a partial resurgence with the housing collapse and great recession of 2008 and the election of Barrack Obama as the 44th President of the United States. Nonetheless, the movement never regained the same level of popularity it had in the 1990s (Southern Poverty Law Center 2009).

The last stream of the American Far Right includes a variety of religious extremists including Christian Identity adherents and anti-abortion organizations. Christian Identity is a warped subset of Christian theology in which Northern Europeans, not the Israelites, are the chosen people of God (Sharpe 2000). Adherents posit that racial minorities existed before Adam and Eve as soulless mud people, and only Caucasians are in the image of God. Further, they believe that Jews are the spawn of Satan through a relationship between Eve and the serpent in the Garden of Eden (Barkun 1997). While Christian Identity churches and congregations remain small, a variety of organizations have expressed their beliefs and engaged in terrorist attacks throughout the United States. Members of the Covenant, Sword, and Arm of the Lord, a Christian Identity commune, attempted to bomb a natural gas pipeline and had plans to poison a large public water supply in the late 1980s (Noble 2010). Many of these groups believe in a coming racial war, based on the interpretation of *The Turner Diaries*, a racist novel depicting a revolution against a corrupt government controlled by Jews and minorities in the United States (Berger 2016; MacDonald 1978).

The latter part of the Christian fundamentalist stream comprises the extreme portion of a mainstream element of the conservative far-right's agenda against abortion in the United States (Perliger 2012). However, antiabortion groups like the Army of God, a leaderless organization responsible for the deaths of physicians and the bombings of abortion clinics, emphasize the lengths some members are willing to go to stop what they term the "abortion industry" (Munson 2008). Antiabortion activists traditionally present their actions, including violence, as acts which aim to save the unborn children (Winter 2014). The most notable members include Reverend Michael Bray, an outspoken advocate and upporter of violence against abortion clinics and physicians, and Scott Roeder, an activist who shot and killed Dr. George Tiller, a physician known for his willingness to perform late-term abortions, in 2009.

The American Far Right is a significant part of the terrorism landscape in the United States. Perliger (2012) chronicled over 4400 cases of far-right violence and property crime from 1990 to 2012. Further, Sweeney and Perliger (2018) believe that much of the activity occurs spontaneously, without planning or premeditation. Regardless of the perpetrator's planning, the far right has shown considerable prowess in engaging in violence in the United States. Notably, the "alt-right," the newest manifestation of the American Far Right, encourages people to commit acts of violence through online social media platforms (Perliger 2017a, b). Since 2016, the alt-right has staged free speech rallies and pro-President Trump rallies, attracting violent elements of the far right and far left and leading to violent street battles between the alt-right and Antifa, a far-left anti-fascist movement (Swenson 2018).

The American Far Left, Anarchists, and Environmental Groups

The American Far Left includes "groups or individuals that embrace anticapitalist, Communist, or Socialist doctrines and [seek] to bring about change through violent revolution" (Department

of Homeland Security 2009, p. 6). Throughout the twentieth century, the United States experienced multiple waves of far-left terrorism which were promoted mainly by a variety of Marxist and Leninist groups, but occasionally also by anarchists and members of animal and environmental rights groups. While the popularity of these groups fluctuates greatly, far-left terrorism was an acute threat mainly in the 1970s and early 1980s, when it was responsible for three-fourths of all officially designated acts of domestic terrorism (Seger 2001).

Probably the most known American Far-Left group was the Weather Underground, which operated in the early to mid-1970s and was comprised mainly from students from Ivy League universities and engaged in bombing campaigns of FBI offices and other symbols of the federal government (Forest 2012). The organization which was a militant advocate against the Vietnam war and other cold war policies also aimed to increase awareness to American imperialistic, racist policies and the negative impact of consumerism and capitalist doctrine. It eventually faded in 1977 as a result of growing pressure from law enforcement, the end of the Vietnam war, and the decline of the New Left movements all over the globe (Forest 2012).

Anarchism is "a philosophy that advocates for complete liberty, freedom, and equality" without government or the traditional Westphalian concept of statehood (Borum and Tilby 2005, p. 202). In the United States, anarchism has experienced popularity mainly in the early twentieth century, a trend which also was manifested via violent attacks against symbols of the American polity and capitalist system. The assassination of President McKinley in 1904 by an anarchist activist is a case in point, as well as the September 16, 1920 attack in Wall Street, when a cart exploded in front of the J. P. Morgan and Chase Company headquarters in New York City (Federal Bureau of Investigation 2010; Forest 2012). The intended target was J. P. Morgan, whom anarchists viewed as a symbol of capitalism. However, he escaped without harm, which was not the case for the seven fatalities and dozens of injured. The movement's eventual decline later in the mid-1920s was due to a lack of coordinated effort against aggressive government intervention through laws which outlawed anarchist speech (Colson 2014).

Since the mid-1980s, environmentalist and animal rights groups began to increase their activities in the United States. While organizations such as *People for the Ethical Treatment of Animals* and *Greenpeace* primarily operate within the boundaries of the law (Liddick 2014), some other associations preferred to utilize violence and illegal practices. The Earth Liberation Front (ELF) and Animal Liberation Front (ALF) use property damage and acts of harassment and threats against individuals and organizations they believe are abusing animals or destroying the environment to achieve their goals (Liddick 2014). Both the ELF and ALF emerged in the United States in the 1990s and expanded significantly in the 2000s, leading the Congressional Research Service to identify these movements as a leading security threat to the United States (Bjelopera 2013, 2014), especially as they expanded their engagements in acts of arsons, bombings, and property damage (Carson et al. 2012).

Jihadi Terrorism in the United States

Religious terrorists twist the underlying interpretation of religious scripture to justify violence. In the United States, there are many examples of religious terrorism, particularly among the American Far Right, but Islamic Jihadi terrorism has taken the preeminent position in the United States. Islamist extremists use interpretations of Koranic verses to justify their violence as defending Islam, or they interpret the verses as requiring the expansion of Islamic control throughout the world. Traditionally referred to as the global jihadist movement, Islamist extremists have targeted the United States since the 1970s. However, until the 1990s, much of the violence targeted American institutions abroad, and the attacks involved non-US citizens.

In the 1990s, Osama Bin Laden, the former leader of Al-Qaida, issued multiple declarations

of war against the United States for its military presence in Saudi Arabia and the invasion of Iraq during the Gulf War. Following the September 11, 2001 attacks, Al-Qaida and other jihadist organizations have inspired domestic attacks inside the United States. Domestic jihadist attacks involve individuals who did not enter the United States with the purpose of committing an attack, but they became inspired to commit acts of violence for the jihadist cause. In 2009, Major Nidal Hassan, a psychiatrist with the US Army, opened fire on soldiers and civilians at Fort Hood near Killeen, Texas. Hassan killed more than a dozen people before law enforcement wounded Hassan. The resulting investigation revealed Hassan was in contact with Anwar Al-Awlaki, an American citizen and al-Qaida operative in Yemen, who encouraged the attack. The Islamic State has also encouraged attacks in the United States. In 2016, Omar Mateen killed almost 50 people in the Pulse Nightclub in Orlando, Florida. Shortly before beginning his mass shooting, he called law enforcement and pledged his allegiance to the Islamic State. While these are only two incidents, they represent the type of mass casualty attack jihadist ideologies have inspired since September 11, 2001.

Ethnic Terrorism

Ethnic violence in the United States is less common than violence associated with other ideologies. However, two movements have engaged in violence in the United States in the name of an ethnic group or a nationalist goal. The first is Puerto Rican Separatists who seek Puerto Rican independence from the United States, and the establishment of a Marxist or socialist government in Puerto Rico. For example, the Fuerzas Armadas de Liberación Nacional ("Armed Forces of National Liberation"), or the FALN, engaged in multiple bombings, robberies, and weapon violations in the 1980s and is still considered the most prolific terrorist group which ever operated in the United States. In 1980, authorities arrested a dozen FALN members in Illinois on charges of robbery, conspiracy, and weapon violations. The arrests resulted in numerous convictions on a variety of charges, but due to violations of legal practices by the Federal Bureau of Investigations' investigation into the FALN, President Bill Clinton commuted the sentences of 14 FALN members in 1999 (González-Cruz 2008). Today most Puerto Rican Nationalists engage in non-violent activism.

The second movement is the Chicano Separatist Movement, which seeks to claim ndependence for territory known as Aztlán in the Southwestern United States. While the Chicano Separatist Movement has no centralized extremist organizations, single members have engaged in terrorist violence in the United States. For example, in the 1960s, Reies López "El Tigre" Tijerina, leader of the Alianza Federal de las Mercedes ("Federal Alliance of Land Grants"), took two US park service rangers hostage in the Kit Carson National Forest to protest the federal government's transition of lands from the local community into a national forest (Trivett 2014). Tijerina and his followers put the two park rangers on trial for trespassing. Following the trial, federal authorities quickly arrested those involved which led to a downfall in the use of criminal tactics by Tijerina and much of the Chicano Separatist Movement (Trivett 2014). Currently, the movement seeks non-violent and protest activities, focusing on the rights of Latinos in the United States and expanded protections for undocumented and illegal immigrants (Trivett 2014).

Conclusions

While domestic terrorism in the United States was manifested in the name of various ideological agendas, since the beginning of the twenty-first century, the far right, Jihadi, and environmental associations dominate the violence. Moreover, while Jihadi violence is perpetrated mainly by inspired individuals, the American Far Right and the environmental movement consist today of multiple organizations with significant differences regarding their ideological origin, organizational structure, and preferred tactics.

Also, it seems that most domestic terrorism today is perpetrated by groups which are increasingly decentralized and thus provide more of a general ideological and logistical infrastructure rather than direct guidance for specific acts of political activism. It seems that the dramatic changes in modern communication technology also facilitated this process of decentralization, as it allowed ideological movements to establish virtual communities where members can pick and choose the type of ideas and activities they are interested in promoting.

Lastly, the growing political polarization in the American political system and populace may further incentivize and legitimize militant manifestation of political activism and thus provide greater operational space for domestic groups who are considering the use of violent tactics.

Homegrown violent extremist · Foreign terror organization · Radicalization

Definition

Homegrown terrorism is acts of terrorism targeting the citizens, institutions, or government within the country in which the terrorist resides. Homegrown terrorism falls into two categories: *domestic terrorism* and *homegrown violent extremism (HVE)*.

- *Domestic terrorism* is acts of terrorism inspired by the US-based movements that espouse extremist ideologies of a political, religious, social, racial, or environmental nature. (Federal Bureau of Investigation, 2018)*
- *Homegrown violent extremist* (HVE) refers to a US-born or naturalized citizen who is inspired by the ideology of a foreign terror organization to commit acts of terrorism targeting the citizens, institutions, or government within the United States. Many HVEs act independently and do not receive any financial or operational support from the foreign terror organization (Bjelopera, 2018).

Foreign terror organization (FTO) is a label designated by the US Secretary of State to foreign organizations that engage in terrorist activity which threatens the security of US nationals or the national security of the United States (Department of State, 2018).

Left-wing terrorism involves acts of terrorism based on extreme interpretations of left-wing ideologies, including anti-capitalism, anti-imperialism, revolutionary communism or socialism, and anarchism. These ideologies are primarily revolutionary and use violence to eliminate what they believe to be social or class inequality.

Right-wing terrorism is acts of terrorism committed in support of extreme interpretations of right-wing ideologies, including racial supremacy, ethno-nationalism, and anti-government sentiment. Ethno-nationalist extremists employ a radical support for the political interests of a particular ethnic group.

Religiously motivated terrorism involves acts of terrorism based on the extreme interpretation of any religion or faith-based belief system. The terrorists justify the violence as being required by their religious dogma. There have been extremists in all major religions who have used violence in support of their radical religious beliefs.

Single-issue terrorism involves act of terrorism committed for a singular issue, including anti-abortion, animal rights, and environmental issues.

Introduction

Terrorism is a tactic which has been used throughout the world by individuals and groups willing to use violence and/or the threat of violence to create fear in a population for the purpose of causing political or social changes. There is no universally accepted definition of terrorism, but most definitions regard terrorism as an act that involves the threatened or actual use of ideologically motivated violence or illegal force used to accomplish political, social, or religious objectives.

Homegrown terrorism falls into two distinctly different categories: domestic terrorism and homegrown violent extremism. US law enforcement agencies categorize acts of domestic terrorism separately from attacks by homegrown violent extremists. Domestic terrorism is acts of terrorism inspired by US-based movements that espouse extremist ideologies of a political, religious, social, racial, or environmental nature (Federal Bureau of Investigation, 2018).

Homegrown violent extremism, in contrast, involves US-born citizens, naturalized citizens,

*Domestic terrorism is examined more fully in a separate section of this encyclopedia.

or citizens residing within the United States who are influenced to commit acts of terrorism by the extremist beliefs espoused by FTOs (Bjelopera 2018). A current example of a HVE in the United States is the religiously motivated threat from foreign terror organizations al-Qaeda and the Islamic State.

Homegrown Terrorism Ideologies

Throughout history, there have been notorious examples of individuals and groups engaging in unlawful acts of terrorism. Acts of terrorism are most often attributed to groups or individuals who espouse an ideology or belief system which they use to justify their actions. These ideologies can be described and categorized based on the nature of their extremist beliefs. Most frequently, they are labeled as right-wing, left-wing, religiously motivated, and single issue. These ideologies are extreme interpretations of legitimate, non-violent causes.

Right-wing extremist ideologies include racial supremacy, ethno-nationalism, and anti-government sentiment. In the United States, between 2007 and 2016, 74% of the 372 people killed by domestic extremists were killed by right-wing extremists (Anti-Defamation League 2016). According to Europol, the number of arrests for right-wing extremism in European countries rose from 12 in 2016 to 20 in 2017. It is believed that the recent rise in right-wing extremism was triggered by the influx of Muslim refugees and fear of the Islamization of Europe (Europol 2018).

Left-wing ideologies include anti-capitalism, anti-imperialism, revolutionary communism or socialism, and anarchism. The extremist interpretation of these ideologies advocates violence against government institutions or targets that represent capitalism. Between 1970 and 2016, 41 police officers in the United States have been killed by left-wing extremists (Anti-Defamation League 2016).

Religiously motivated terrorism based on the extreme interpretation of religious dogma has become a prominent threat against western societies. The terrorists justify their use of violence as being required to defend their religious beliefs. There have been extremists in all major religions who have used violence in support of their radical religious beliefs.

Single-issue terrorism committed by anti-abortionists, animal rights advocates, and environmental activists is unlike right-wing, left-wing, and religiously motivated terrorism because of its singular issue. These extremists are not seeking broader political or religious change. They only seek to cause changes to their primary cause.

The US Constitution protects American citizens' ability to seek out and adopt messages from individuals or groups that advocate terrorism, violence, or other unpopular ideologies. It is only when those citizens violate or attempt to violate state or federal laws in furtherance of those ideologies that their constitutional protection ends. American citizens are free to speak in favor of terrorist groups or agendas, but if they take action that violates the law, such as providing support to terror groups, committing crimes in furtherance of a terror organization, or recruiting others to do so, those citizens may be subject to prosecution (Federal Bureau of Investigation, 2011).

Radicalization to Terrorism

Radicalization happens when an individual accepts an ideology that advocates violence to cause societal change and then becomes motivated to commit violence (U.S. Department of Homeland Security 2016). The process of radicalization can begin through social or familial contacts who promote the extremist ideology or by self-radicalization. The ubiquitous nature of modern communications technology, the Internet, and social media facilitates self-radicalization. Individuals residing in the United States can now become fully immersed in conflicts and ideological causes occurring in foreign countries with no, or very little, censorship or delay in the message. Constant communications from foreign organizations reach susceptible individuals who may be enticed to join a cause that is unpopular in

United States (International Public Safety Association 2018).

The FTOs al-Qaeda in the Arabian Peninsula (AQAP) and the Islamic State in Iraq and the Levant (ISIL) have become particularly adept at producing jihadist messages that target American and European individuals who might be susceptible to radicalization. Social media outlets provide terror organizations and their supporters the ability to exchange extremist propaganda and rhetoric with a like-minded global audience. A recent study by the National Consortium for the Study of Terrorism and Responses to Terrorism (START) shows that American Islamic extremists had a higher rate of Internet radicalization than right-wing or left-wing extremists (START 2017). Online jihadi videos such as those posted by American-born cleric Anwar al-Awlaki sought to motivate and inspire people to adopt al-Qaeda's radical extremist ideology. Al-Awlaki, who was targeted and killed by a US drone strike in 2011, is believed to have inspired several notorious terror events, such as the 2009 Fort Hood shooting, the 2009 Christmas Day bomb plot, and the 2013 Boston Marathon bombing (Shane 2015).

Online magazines, such as *Inspire* magazine produced by AQAP (Hunter & Heinke, 2011) and *Rumiyah* magazine produced by ISIL, are written in the English language and target individuals living in western countries. A typical edition of these magazines contains articles and photos that justify and advocate the commission of violence, assassinations, murder, and mass murder against anyone who does not share the group's extreme religious views. They contain detailed instructions on methods to construct weapons and tactical advice for the commission of atrocities. The pressure cooker bombs used in the 2013 Boston Marathon bombing were similar to designs found in an *Inspire* magazine article "How to Build a Bomb in the Kitchen of Your Mom." It is legal to download these online magazines in the United States, but other countries such as the United Kingdom and Australia have prosecuted individuals for possession of the jihadist material.

To develop an understanding of HVEs, researchers examine how and why people become terrorists and look for factors which may cause the transition from being a lawful citizen to one who engages in violent and criminal behavior in furtherance of a cause. Attacks have been perpetrated by individuals from a wide range of ethnic, social, educational, and economic backgrounds. There have been several studies that have examined the radicalization of recent HVEs, but these studies are usually hampered by limited data sets and restricted access to the actual perpetrator. Without access to the person who has become radicalized, researchers sometimes rely on indirect evidence to develop their theories. While there are several explanations of the process to radicalization, researchers have not found any conclusive single reason that would explain why individuals would embrace the narrative of a foreign terror movement and then willingly engage in the support of, or the commission of, violent terror activity (Borum, 2012).

Recent examples of religiously motivated HVEs in the United States have become radicalized only after they converted to a new religion. Colleen LaRose, who became known as "Jihad Jane," adopted the Islamic religion as an adult. She was born and raised in Michigan, but after her conversion to Islam, she became radicalized and used the Internet to recruit other people to wage violent jihad. LaRose participated in a plot to murder a Swedish artist who had drawn a representation of the Prophet Muhammad. LaRose was sentenced to 10 years in prison after pleading guilty to terror offenses in US federal court. (Federal Bureau of Investigation 2014).

Bryant Neal Vinas was born in New York to parents who emigrated from South America. He was raised as a Catholic, but he converted to Islam as an adult and began using the name Ibrahim. Vinas is believed to have radicalized after viewing jihadist material on the Internet. He traveled to Pakistan and attended a terrorist training program where he worked with al-Qaeda planners to develop a plot to bomb the Long Island Rail Road in New York. Arrested before he could carry out his attack, Vinas plead guilty to conspiracy to murder and other terrorism offenses (Federal Bureau of Investigation 2016).

Examples of Homegrown Violent Extremism

Following the terror attacks of September 11, 2001, the United States has seen an increase in incidents of religiously motivated homegrown violent extremism, specifically those inspired by the terror groups al-Qaeda, Islamic State, or their affiliates. Testifying before the Senate Homeland Security and Government Affairs Committee, FBI Deputy Assistant Director Nikki Floris stated that the FBI "views the Islamic State of Iraq and Syria (ISIS) and homegrown violent extremists as the main terrorism threats to the United States" (Federal Bureau of Investigation 2017, p. 1).

The following cases are examples of individuals who have committed acts of terrorism against targets in their native or adopted country and have been motivated by extremist ideology of a FTO and were exposed to radical beliefs or posted radical messages online:

New York City Vehicle Attack – On October 31, 2017, Sayfullo Saipov drove a rented truck onto a bike path and pedestrian walkway in New York City, intentionally killing 8 pedestrians and injuring 12 others. Saipov was a legal resident of the United States after he emigrated from Uzbekistan in 2010.

When the truck that Saipov used in the attack collided with a school bus, he exited the vehicle yelling "Allahu Akbar" while brandishing what appeared to be two handguns but were in fact pellet and paintball guns. New York Police Department officers at the scene shot Saipov and arrested him before he could continue his attack. Investigators recovered Saipov's cellphones which contained videos and images of Islamic State propaganda and also showed Internet searches of New York City and Halloween.

After his arrest, Saipov confessed to planning the attack for over 1 year and that he had been inspired to commit the terror attack by ISIS videos. His plan was to kill as many people as possible on the pedestrian walkway and then proceed to the vicinity of the Brooklyn Bridge to kill additional pedestrians. He explained that he intentionally chose to commit his attack on Halloween, believing there would be more pedestrians on the streets. Saipov also stated that he felt good about what he had done in the attack (U.S. Department of Justice 2017).

Saipov's terrorist attack closely mirrored instructions found in the November 2016 edition of the ISIS magazine *Rumiyah*, which contained an article called "Just Terror Tactics." The article provides detailed instructions for the planning and execution of terror attacks using a vehicle as a weapon to kill non-believers. The article also advocates that the attacker should exit the vehicle when it can no longer be driven and continue the attack with handheld weapons (U.S. Department of Justice 2017).

Westminster Attack – On March 22, 2017, British-born Khalid Masood drove a vehicle across Westminster Bridge in the direction of the Palace of Westminster in London. Masood drove the vehicle onto the pedestrian walkway, intentionally striking pedestrians. He then crashed his vehicle into the perimeter fence of the Palace of Westminster, which is the meeting place of the United Kingdom's Houses of Parliament (Hill, 2018). Masood exited his vehicle and fatally stabbed an unarmed police officer before he was shot by another armed officer. The attack killed 5 victims and injured 50. Khalid Masood was born Adrian Russell Elms but changed his name upon conversion to Islam. Investigators discovered that Masood had posted jihadi messages on social media but found no indication that he had any direct instructions from al-Qaeda or the Islamic State (Metropolitan Police 2017).

Pulse Nightclub Shooting – At approximately 2:00 a.m. on June 12, 2016, Omar Mateen entered the Pulse nightclub in Orlando, Florida, and began shooting at patrons. Between the time he began his murderous attack and the time when he was killed by responding police officers, he had killed 49 people and wounded 53. This was the most lethal mass shooting in US history at the time. While Mateen was inside the nightclub, he made

two calls to Orlando Police in which he identified himself as an Islamic soldier and repeatedly pledged allegiance to Abu Bakr al-Baghdadi, the leader of the Islamic State. Mateen also told the police that he had an explosive vest similar to those used in the Paris terror attack and that a vehicle outside the club had explosives that would kill the police. Neither statement about the explosives was true, and no explosives were found by responding officers.

Mateen was born in New York and then moved to Florida with his family when he was 5 years old. He attended primary and secondary school in Florida and had several reports of behavioral issues. After graduation from high school, Mateen received a degree from Indian River State College and was working for a private security company at the time of the shooting.

The FBI reported that Mateen became radicalized by watching online jihadi videos. Although the Islamic State of Iraq and Syria claimed responsibility for the attack, investigators found no indication that Mateen had any contact with, or direction from, a FTO (Washington Post, 2016).

San Bernardino Shooting – On December 2, 2015, Syed Farook and Tashfeen Malik, a married couple, conducted a mass shooting at the Inland Regional Center in San Bernardino, California.

Syed Farook was employed as a Health Inspector by the San Bernardino County Department of Public Health and was present at the Inland Regional Center for a combined training session and holiday party on the day of the attack. He left the training session early without explanation but left his backpack on the table. Approximately 30 min later, Farook and Malik returned to the building, armed with assault rifles and wearing tactical clothing and masks. They entered the room and began shooting. They fired over 100 rounds, killing 14 people and injuring 22 others before fleeing the scene in a rented SUV.

After the shooting, the pair drove the SUV throughout the San Bernardino area until they were spotted by police officers. Approximately 4 h after the initial shooting, the couple stopped their SUV and initiated a violent shootout with police officers. Both Farook and Malik were killed. A triggering device was found in the vehicle. Farook's backpack, which he left at the Inland Regional Center, contained a remotely controlled improvised explosive device, but it was rendered safe by the responding bomb squad (Department of Justice 2016).

The FBI reports that the couple had become radicalized for at least 3 years prior to the attack and spent over 1 year making financial and tactical preparations. Prior to the attack, Ms. Malik used Facebook to declare her allegiance to the Islamic State (Nagourney et al. 2015).

Fort Hood Shooting – On November 5, 2009, 12 US service members and 1 civilian employee were killed and 32 were wounded in a mass shooting at the military base at Fort Hood, Texas. The shooter, Nidal Hasan, was a psychiatrist and a Major in the United States Army.

Hasan was born in Virginia and attended Virginia Tech University. After graduating with an Engineering Degree, he joined the US Army. In 1997, he entered medical school at the Uniformed Services University of the Health Sciences. During his medical residency at Walter Reed Army Medical Center and at subsequent assignments, Hasan's colleagues and superiors were aware of his growing violent Islamic extremism, but a post-attack investigation by the FBI and the Department of Defense showed that no action was taken against Hasan despite his troubling behavior (U.S. Senate Report 2011).

The investigation of Hasan revealed that he had become radicalized gradually over a period of several years, but the radicalization escalated in the 2 years prior to the attack. In 2007, Hasan was scheduled to deliver a presentation on a healthcare topic to fellow officers. Hasan's presentation was stopped after 2 min because of protests from the audience. Instead of a healthcare topic, Hasan's presentation espoused radical Islamic views,

including defending Osama bin Laden, justifying suicide bombings, and blaming the United States for problems in the Middle East (U.S. Senate Report 2011). Hasan sent messages to al-Qaeda associate Anwar al-Awlaki using Awlaki's website and participated in an essay contest praising Awlaki's leadership (Poppe 2018).

While religiously motivated extremism has been the prominent threat to the United States over the past few decades, historic review of terrorism trends shows that the threat is constantly changing and adaptive. Therefore, the possibility exists that HVEs motivated by foreign ideologies other than religion could threaten the United States in the future.

Conclusion

Homegrown terrorism involves individuals committing acts of terrorism that target the citizens, institutions, or government of the country in which they reside. Homegrown terrorism generally falls into two categories: domestic terrorism, which is motivated by domestic issues, and homegrown violent extremism.

Homegrown violent extremists are individuals who live and operate in the United States and engage in, or attempt to engage in, illegal terrorist activities and are inspired by the ideology of a foreign terror organization. Many HVEs act independently and do not receive funding or operational direction from the FTO. HVEs are distinct from domestic terrorists in that they adopt the ideology of a FTO, while domestic terrorists adopt the ideology of US-based movements.

There has been an increase in cases of religiously motivated homegrown violent extremism since the terror attacks of September 11, 2001. Most of these cases involve individuals inspired by the infamous attacks against the United States and other western nations by the terror group al-Qaeda, the Islamic State, or their affiliates.

While religious extremism has recently been a prominent motivation of HVEs in the United States, historic review of terrorism trends shows that the threat is constantly changing and adaptive. Therefore, the likelihood exists that HVEs with ideologies other than religion will threaten the United States in the future.

Definition

Premeditated, politically motivated violence perpetrated against noncombatant targets by individuals and/or groups inspired by, or associated with, designated foreign terrorist organizations or nations.

Introduction

Most terrorist groups that were active before WWII operated in a single country or region. However, with the proliferation of Left-Wing and Religious groups in subsequent decades, a growing number of terrorist organizations started to operate in multiple countries, thus forcing law enforcement and scholars to address and explore terrorism also in an international context. Title 22 of the United States Code, Section 2656(d), defines terrorism as "premeditated, politically motivated violence perpetrated against noncombatant targets by subnational groups or clandestine agents," further providing that *international* terrorism is a "terrorism involving citizens or the territory of more than one country." For example, if the American Sovereign Citizens Movement attacked a mosque in Los Angeles, that would be classified as a domestic terrorist attack, whereas if members from the same group traveled to Saudi Arabia to attack a mosque in Riyadh, that would be considered by most law enforcement organizations and legal authorities as international terrorism. Academics, however, seem to be more skeptic about the distinctions between domestic and international terrorism. Many tend to point out that the increasingly globalized nature of many terrorist organizations and their cellular structure make it difficult to determine if acts or campaigns of terrorism are executed by domestic or international actors.

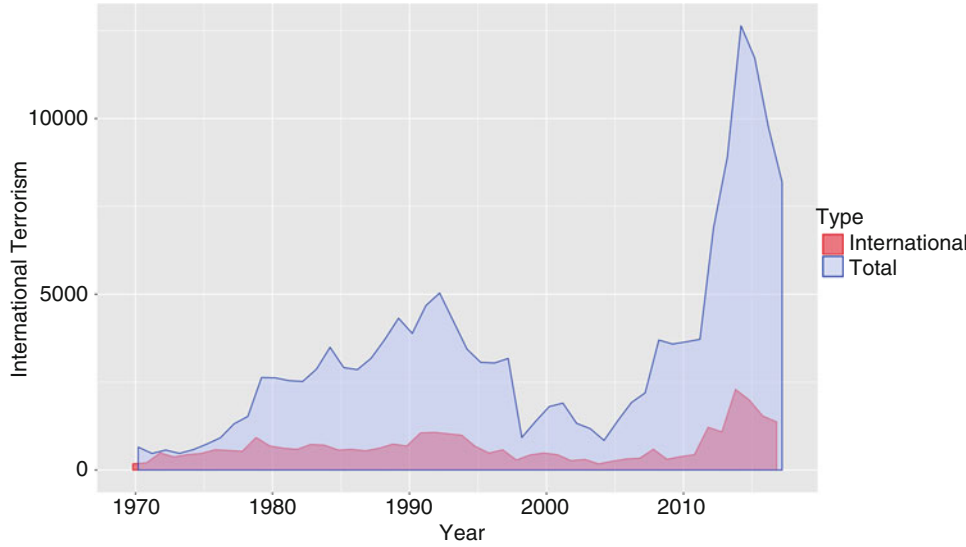
More specifically, while the statutory definition accounts for citizens and territories of multiple states, it fails to address cases in which militant ideology crosses state boundaries. For example, Alexander Blair and John T. Booker were American citizens charged with terrorist-related activity. After they were exposed to online propaganda of Jihadi groups, they posted statements online about their intent to wage jihad and their willingness to die for that cause. Based on the current legal statute, if these individuals were to conduct an attack within the United States, it would be an act of domestic terrorism, despite the influence of international Jihadi groups such as the Islamic State.

As these types of global trends become increasingly prevalent, it is clear that additional criteria need to be utilized in order to effectively distinguish between domestic and international terrorism. To this end, aspects from the Federal Bureau of Investigation's (n.d.) definition can be incorporated to produce a more comprehensive definition of international terrorism as *premeditated, politically motivated violence perpetrated against noncombatant targets by individuals and/or groups inspired by or associated with designated foreign terrorist organizations or nations*.

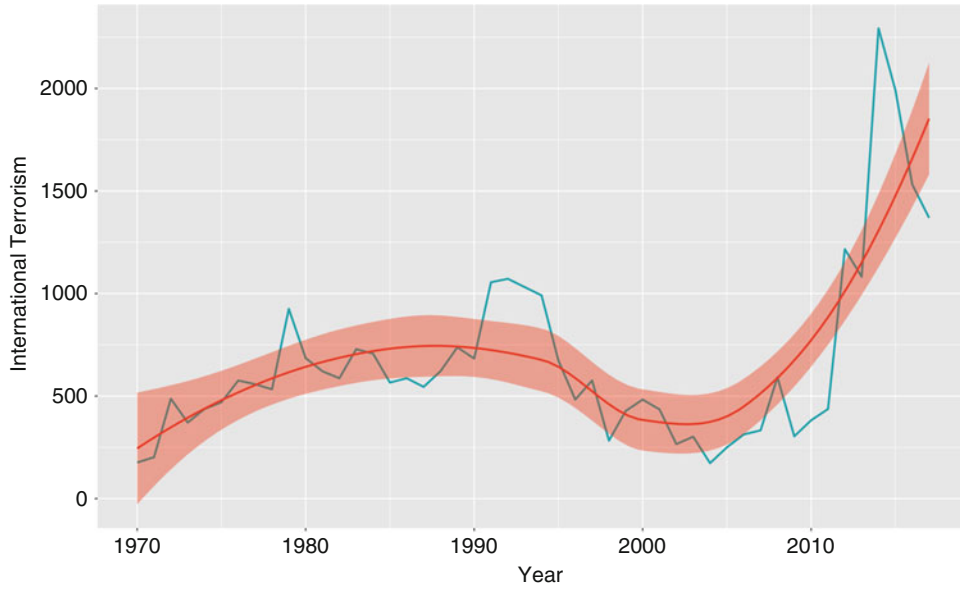
Trends

David Rapoport (2004) identified four historical waves of terrorism: (1) anarchist, (2) anticolonial, (3) leftist, and (4) religious. The first two ideological waves were inherently intrastate; the motivations for violence focus on specific geographic or political grievances (such as ethnic, separatist, or political slant). Left-wing terrorism, however, focused on the ideals of class struggle and individual empowerment within the framework of rejecting the nation-state model, concepts that transcend national boundaries. Both "class" and "religion," however, are social constructs, specific to certain times and geographic spaces. The power of religious fanaticism as a unifying cause for drawing support from a broader religious community has resulted in unprecedented levels of militancy (Ranstorp 1996); this can be seen through the activities of several international terrorist organizations, such as Al-Qa'ida and the Islamic State. Placed into context, in 2016, more countries than ever before experienced at least one death attributed to terrorism (Institute for Economics & Peace 2017).

Both international and domestic terrorism follow similar trends, as seen in Fig. 1: generally increasing from 1970 through 2017, with a brief period of decline during the 1990s. From roughly 2001 onward, terrorist activity has continued to increase at a rapid pace, with a global climax in 2014. International terrorist trends, in particular, have varied on a year-to-year basis, as shown in Fig. 2, but show a drastic increase coinciding



Terrorism: International, Fig. 1 Terrorist activity, total and international (1970–2017)

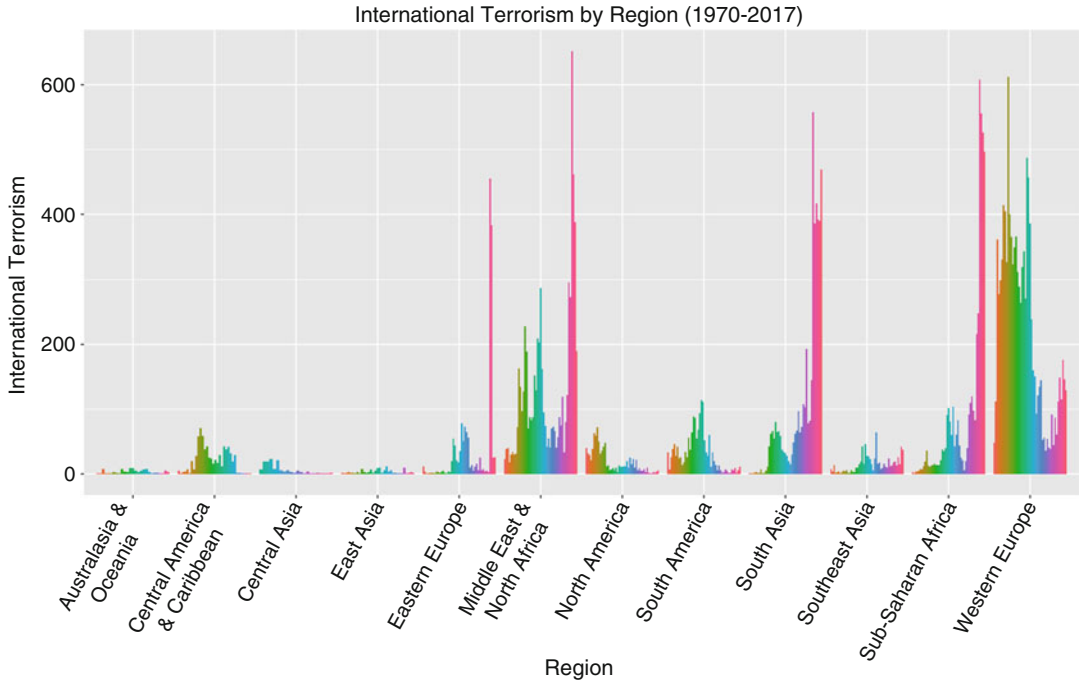


Terrorism: International, Fig. 2 International terrorism over time with mean slope (1970–2017)

with the proliferation of attacks by transnational extremist ideological actors such as Al-Qa'ida, the Islamic State, and their splinter organizations.

Geographical Focus

In the context of international terrorism, most experts identify the Middle East and North Africa as the regions which produced the highest number of attacks, as seen in Fig. 3. Moreover, many of the Middle Eastern groups also engaged in concentrated efforts to expand their operation into Western countries such as the United States and some of the dominant European nations (such as the UK, France, and Germany). Some of these



Terrorism: International, Fig. 3 International terrorism by region (1970–2017)

attacks were justified by militant religious convictions, while others were justified by the perceived Western exploitation of, and intervention in, countries in the region. The increasing capabilities of organizations such as Al-Qa'ida and the Islamic State further reflects that not as in the 1970s and 1980s, the proliferation of terrorism in the Middle East eventually impacted countries outside this region. Additionally, sustained military interventions in places such as Iraq, Afghanistan, and Lebanon also triggered retaliation in the form of international terrorism. For example, following the assassination of Abbas al-Musawi, the first leader of Hizbullah, by Israeli military forces, the organization retaliated by bombing and demolishing the Israeli embassy in Argentina and the Jewish community building in Buenos Aires, in 1992 and 1994, respectively. Similarly, the western coalition's military campaign in Iraq, which began in 2003, inspired retaliation by Western Jihadists, including the London 7/7 bombers.

The instability and internal conflicts in Afghanistan since the late 1970s, and the ongoing conflict between Pakistan and India, were some of the major factors which also led South Asia to experience exponential growth in the number of international terrorist incidents in the last few decades. For example, despite continued military intervention strategies from multiple countries, Pakistan's Federally Administered Tribal Areas (FATA) region remains a safe haven for transnational threats, such as Al-Qa'ida and the Taliban (Acharya et al. 2009; Gunaratna and Nielsen 2008; Rana 2009). Similarly, India has been plagued with terrorist-perpetrated violence. In 2008, Lashkar-e-Taiba, a Pakistan-based Islamic terrorist organization, engaged in a sustained shooting and bombing campaign at targets throughout the city of Mumbai, India. These individuals traveled to India specifically for the purpose of conducting this attack. While India did not take retaliatory military action against Pakistan, this situation further corroded trust between the two nations, impacting Indo-Pakistani relations (Javaid and Kamal 2013). Seven years earlier, Lashkar had engaged in an attack on the Indian Parliament in New Delhi in conjunction with Jaish-e-Mohammed, another Pakistan-based

group. This represents the spillover of diplomatic hostilities into asymmetric conflicts; India and Pakistan have historically had tense relations over multiple issues, most notably the disputed status of the accession of Jammu and Kashmir. Hence, Lashkar was a creation of the Pakistani Military Intelligence (ISI), which was looking in the late 1980s for ways to destabilize Kashmir, without being perceived as directly involved (Blank 2013).

Contradicting dynamics can be identified in other geographic regions, such as Central and East Asia, Australasia and Oceania, and Central America and the Caribbean. All these regions have actually seen decreases in victimization by international terrorism over time. It is not clear if this decline will persist, as some scholars argue that such dynamics may be cyclical. Feichtinger and Novak (2008), for example, assert that in the long run, government-terrorist dynamics remain in persistent oscillations, suggesting that a rise in terrorist activity in these areas may be on the horizon, as seen in areas like Eastern Europe and Southeast Asia where declines were followed by rising trends again.

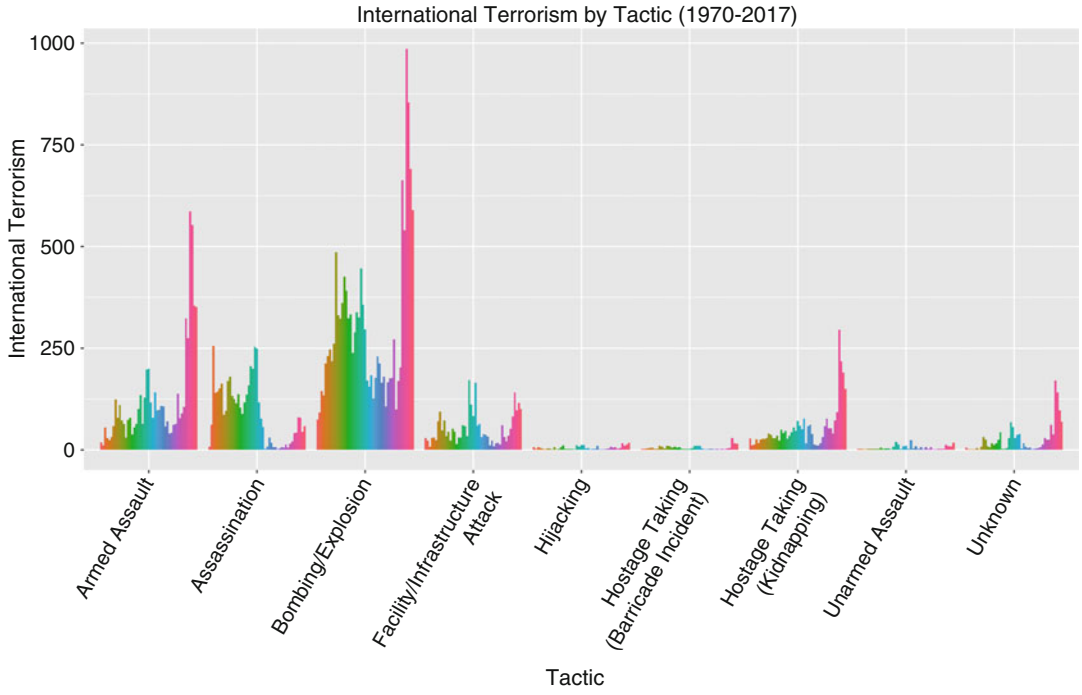
To conclude, international terrorism remains associated with weak and failed states (see Newman 2007). Contemporary examples include countries, such as South Sudan, Somalia, Libya, and Yemen (see Messner et al. 2018). Specifically, Piazza (2008) found that failed states are statistically more likely to (1) host international terrorist groups, (2) have their nationals commit international attacks, and (3) be targeted by international terrorists themselves. For example, Syria is a country engulfed in intrastate conflict. The Islamic State actively operates and engages in violence within Syria but also plans and perpetrates attacks globally. Beyond its own citizens joining these radical groups, individuals from around the planet have sought to travel to Syria to join ISIS (Binetti 2015; Franz 2015; Noonan and Khalil 2014; Patil and Ennis 2016).

Tactics

The tactics employed in campaigns of international terrorism vary broadly. However, a close examination reveals that some tactics experience a contingency effect and are quickly adopted by organizations if proven effective in previous or contemporary campaigns. The tactic of suicide bombing proliferated and was adopted by an array of organizations (such as LTTE and Hamas) after Hizbullah demonstrated its effectiveness in the early 1980s in its attacks in Lebanon (Pape 2003). Furthermore, Fig. 4, which provides insight into the usage of tactics by international terrorism over time, reflects crossover between tactics. For example, attacks involving targeting facilities and those with hostages often include overlap with other tactics.

Facility/Infrastructure Attacks are resurging, despite a previous decline. In 2009, Nidal Hasan fatally shot 13 people at Fort Hood in Texas, inspired by Jihadi Ideology Anwar al-Awlaki. One of the most common types of attacks is the targeting of Embassies and similar diplomatic and military facilities. In 2012, members of the Libya-based Ansar al-Sharia group attacked the United States Embassy in Benghazi, Libya, resulting in the death of the US ambassador and three other US citizens. Since the embassy itself is considered US territory, deaths occurring inside the embassy would be attributed to international terrorism. Similar attacks are the 1998 suicide attacks against the American embassies in Dar es Salaam, Tanzania, and Nairobi, Kenya, by Al-Qa'ida, as well as the attacks against the American embassies in Tehran and Islamabad in 1979. In both of the latter cases, radical college students stormed the US embassies taking diplomats as hostages (In Iran) or looking to harm the diplomatic personnel (as was the case in Islamabad when a Marine was killed) (Kohler 2000).

Hostage Taking was a popular tactic during the 1960s and the 1970s, especially in the context of aviation terrorism. Palestinian Nationalist and Left-Wing groups looking for attracting attention to their suffrage and goals mastered the practice of extending the attacks via hostage taking for days and weeks and maximizing the psychological impact and publicity they look to project. The kidnapping and killing of members of the Israeli delegation during the Munich Olympic games in 1972 by the Palestinian-based Black September organization is a case in point. While such kinds



Terrorism: International, Fig. 4 International terrorism by tactic (1970–2017)

of hostage-taking attacks are less popular today, many contemporary terrorist groups aim to kidnap specific individuals for ransom purposes or in order to attract attention to their ideological platform. In 2002, Daniel Pearl was abducted and eventually executed by the National Movement for the Restoration of Pakistani Sovereignty, after being deemed a "spy" of American interests (Musharraf 2006), an attack with lasting implications for US-Pakistani diplomatic relations. Similarly, in 2014, ISIS released videos showing the beheadings of two kidnapped American journalists, James Foley and Steven Sotloff, which prompted the Obama administration's declaration of retaliatory action against the Islamic State (Abdelaal et al. 2015).

Despite the evolution of military technology, *Bombings/Explosions* are still by far the most extensively employed tactics for engaging in terrorist activity. To execute these attacks, only rudimentary knowledge is necessary for bomb-making purposes, as well as basic know-how knowledge related to intelligence gathering and logistical practices. The proliferation of terror-produced magazines, such as Al-Qa'ida's *Inspire* and ISIS's *Dabiq*, and increasing access to the relevant operational information via online platforms have facilitated easier access to such knowledge (van Dongen 2016). For example, Dzhokhar Tsarnaev, one of the Boston Marathon bombers, learned how to weaponize pressure cookers from *Inspire*.

More capable organizations have utilized force multipliers in order to enhance the impact of this basic tactic, mainly via the use of suicide bombing and car bombs. The use of such force multipliers does not just help to maximize the damage of the attack but also serves an array of other objectives, such as illustrating the commitment of the organization to the cause, enhancing the symbolic and psychological impact of the violence, and allowing the organization to perpetrate more sophisticated operations. For example, within the radical jihadist movement specifically, suicide bombing has also been associated with martyrdom and the giving of one's entire self to the cause. This form of attack has been used in multiple contexts to build a symbolic narrative to political violence, an

idea that extends far beyond Islam (Khosrokhavar 2005). Research has found that the use of suicide campaigns overwhelmingly helps the terrorist organization's political cause (Pape 2003). The Tamil Tigers, a Sri Lankan-based organization, infamously integrated suicide campaigns into their operations, leveraging suicide campaigns as a source of symbolism to amass support for their cause (Roberts 2005).

Armed Assault is a commonly used terror tactic for extremist groups. This type of attack requires the least amount of planning and coordination while retaining the possibility to inflict high levels of damage. For example, in 2012, operatives of Al-Qa'ida in the Arabian Peninsula attacked an army base outside of Zinjibar city in Yemen, resulting in the deaths of 185 soldiers using firearms. Beyond global trends, Chasdi (2012) also found armed attacks to be the predominant tactic employed by terror organizations in both Algeria and Mali during the late 1990s. This tactic could be particularly appealing to organizations that lack the institutional capacity and resources needed for more coordinated operations or for individuals seeking to operate on behalf of a larger entity, such as assassinations of political leaders or bombings. For instance, in December 2015, 14 individuals were killed in a mass shooting "rampage" at a county-level government office in San Bernardino, California, by a married couple inspired by ISIS (Morell 2015). This example demonstrates the reach of some international groups, connecting with individuals not actually among their membership ranks (Johnson et al. 2016). For example, Koehler-Derrick and Milton (2017) argue that a group's strategic considerations and resource constraints explain tactic selection. Specifically, they find that groups with larger membership ranks are more likely to use firearms than their restricted counterparts because this tactic exposes the offender to higher levels of risk, such as apprehension or death, than other weapon choices.

The use of *assassinations* as a terrorist tactic has increased threefold from 1945–1969 to the 1970–2013 time period (Perliger 2015). The assassination of political leaders poses a direct challenge to the government's authority. Although this act could have a strong impact, drawing large amounts of attention to the organizational use while simultaneously causing a disruption in routine government operations, assassinations require higher levels of logistical planning than armed attacks. They tend also to intensify the prospects of a state's fragmentation and undermine the democratic infrastructure (Perliger 2015). Assassinations of diplomatic figures stationed abroad can be a mechanism for violent actors to send a powerful message to foreign powers from their own turfs. For example, in 1944, Lord Moyne, the UK's Minister Resident in the Middle East, was assassinated by two members of the Stern Gang or Lehi, a Zionist paramilitary organization focused on the end of British mandate in Palestine (Shpiro 2013). The assassination intensified British sentiments which called for the end of the UK rule of Palestine, a dynamic which eventually led to the end of the British rule in 1947.

Conclusion

While the majority of attention given to international terrorism by the media and political elite focuses on bombings in the Middle East or the Western World, political violence is a global epidemic that has transcended time, with groups employing a variety of tactics to achieve their strategic aims. Additionally, terrorists employ a wide array of tactics in their attacks. Each tactic requires different levels of organizational and tactical capacities, appeals to different types of actors, and impacts the intended targets differently.

Although "jihadism" is the current fascination of policymakers and researchers alike, transnational terrorist operations extend far beyond ideologies associated with radical elements of Islam. States with high levels of international conflict, such as Iraq and Syria (Carpenter 2013; Fearon 2007), alter the true nature of terrorist activity, since terrorism gets crossed with violence associated with the civil wars, providing a "white noise"

effect. The frequency of international terrorism is exponentially growing, increasing the urgency for the development and implementation of new counter-terrorism methods to address the growing threat.

Tort: Property

Adam Scott Wandt
John Jay College of Criminal Justice, New York, NY, USA

Keywords
Tort · Trespass · Conversion · Nuisance · Easements

Definition

1. An unlawful interference by a tortfeasor with the enjoyment of another's private property.
2. A subcategory of torts, relating to damaged property.

Introduction

Damage and interference with land and property is inevitable as members of society regularly interact with one another in public and private forums. We rely on our civil legal system to make victims financially whole through remedies and to influence the way people operate in society (i.e., to be more careful).

This damage and interference may involve another person's real property (i.e., land) or personal property (known as "chattel"). Tort law provides the loss allocation function of defining the conditions under which, and the extent to which, a tortfeasor (i.e., a person who commits a tort) has to compensate an injured party. The law prescribes very specific guidelines for courts to award damages to injured parties. Tort law seeks to aid in the prevention and mitigation of future damage; since remedies are readily available to an injured party, it is hoped that the threat of sanctions will deter a possible tortfeasor from causing damage.

In this entry we will explore the tort of nuisance, trespass to real property, the concept of easements, the doctrine of trespass ab initio, trespass to chattels, defenses to trespass, and the tort of conversion.

A Short History of Property Tort Law

It is believed that the Code of Hammurabi (c. 1754 BCE) (the "Code") is the oldest surviving legal writings of significant length and substance that deal with tort law. The Code is one of the earliest examples of a presumption of innocence and is seen as an early example of fundamental law that regulated ancient society. The Code allows an injured party to respond to a tortfeasor by inflicting a similar type of damage ("an eye for eye, and a tooth for a tooth"). The Code includes remedies for those injured by a negligent builder of a structure that collapses and for one's personal property that is damaged while in the care of a third party. Remedies for torts eventually matured with the introduction of the Roman's Lex Aquilia (c. 286 BCE), the first set of laws that promoted financial compensation of an injured party.

The development of liability for trespass evolved further under the English common law system. Absolute liability (liability regardless of deliberate intent, guilty mind, or harmful acts) was established in *Case of the Thorns* (England, 1466). In that case, a man cut his thorn bush and the thorns fell on his neighbor's lawn. The man walked onto his neighbor's land to retrieve the cut thorns and was held liable for trespass. This case established two important modern concepts: (1) that of absolute liability (i.e., the simple act of entering onto another person's property without authorization constitutes trespass) and (2) that ownership of land entitles an owner to exclude others.

English common law continued to hold that intent is not required for trespass. In *Weaver v. Ward* (England, 1616), the plaintiff and defendant were trained soldiers taking part in a military drill. The defendant accidentally, and against his will, discharged his musket and injured the plaintiff. The court awarded the plaintiff damages, holding that trespass does *not* require intent.

These early systems of law, such as the Code of Hammurabi and Lex Aquila, with influences from other cultures and societies, eventually developed into the English common law and French civil legal systems, which are commonly present throughout the legal world today.

Nuisance

Property owners are entitled to the quiet use and enjoyment of their land. A nuisance occurs when someone interferes with that use and enjoyment, whether through excessive noise, smells, pollution, or other hazard. It may occur during the unreasonable use of one's own property, so that it substantially impairs the rights of another to enjoy their own property. A nuisance is not just the "wrongful invasion of the use and enjoyment of property, but also the wrongful invasion of personal legal rights and privileges generally" (*Taylor v. Cincinnati,* 143 Ohio St. 426 (1944)).

The offensive conduct itself is not the nuisance, but the damage or consequences of the offensive conduct. The condition that creates a nuisance may create a danger to a person, property, or the public welfare.

Nuisance is different than trespass in that a trespass interferes with the rightful possession of property, whereas a nuisance interferes with the use and enjoyment of the property.

A nuisance can be (1) per se or at law or (2) per accidens *or in facts*. "A nuisance per se is an act, occupation, or structure that, by its very nature, is a nuisance at all times and under all circumstances" (*Morgan v. High Penn Oil Co, 238 N.C. 185* (1953)). A lawful act can never be nuisance per se. A nuisance per se can be prevented via legal action at all times. A nuisance per accidens is an act, occupation, or structure that becomes a nuisance by (1) reason of circumstance, location, or surroundings or by (2) the manner it is constructed, maintained, or operated (*Morgan v. High Penn Oil Co, 238 N.C. 185* (1953)).

A nuisance can be (1) private; (2) public; or (3) mixed. A private nuisance is non-trespassory "conduct that interferes with an individual's private right to the use and enjoyment of his or her land" (*Pestey v. Cushman*, 259 Conn. 345, 788 A.2d 496 (Conn. 2002)). Its roots are in property law. A public nuisance is an "unreasonable interference with a right common to the general public" (Rest. 2d). It traditionally interferes with a public right, public health, or public safety. Its roots are in criminal law, and thus claims for

public nuisance are generally brought by governmental units on behalf of the public. An individual may have standing to bring a civil claim for public nuisance if (s)he can show special injury (i.e., harm different from the kind suffered by others exercising the common right, such as physical injury) (*Philadelphia Electric Co. v. Hercules, Inc.* (1985, 3rd Cir)).

An example of a private nuisance is when a person plays loud music late into the evening and keeps his neighbor awake. An example of a public nuisance is a person keeping a very large number of domestic cats on their property or a cattle feedlot that emits noises and odors that waft onto nearby properties and are so strong that landowners are forced inside their houses.

Trespass to Land (Real Property)

The tort of Trespass to Land (i.e., real property) is any unauthorized intentional presence on one's land, or the illegal interference with one's lawful and productive use.

The Restatement of Torts (Second) prescribes:

> One is subject to liability to another for trespass, irrespective of whether he thereby causes harm to any legally protected interest of the other, if he intentionally (a) enters land in the possession of the other, or causes a thing or a third person to do so, or (b) remains on the land, or (c) fails to remove from the land a thing which he is under a duty to remove. (*Restatement of the Law (Second), Torts §158*)

A trespass may be committed on or above the surface of an owner's property. For example, the simple act of walking across a neighbor's lawn without permission is trespass, as is trespass to the air above another's land. In *Herrin v. Sutherland* (1925, MT), a duck hunter shot a gun over another's land and was held liable for trespass. However, for one to be liable for trespass beneath the surface of the land, such as with mining, actual damage is required for liability (i.e., absolute liability does *not* apply).

A trespass can be momentary, continuous, or permanent. For example, a momentary trespass occurs if a lost hiker wanders onto one's property for a few minutes without the owner's permission. A continuing trespass occurs if a person leaves an object or structure on another person's land without the owner's permission, even if the person initially had consent to be on the land (*Rogers v. Board of Road Commissioners for Kenty County* (1947)). To be considered a continuing trespass, the situation must be able to be remedied by restoring the land to its original state (otherwise it would be a permanent trespass). For example, a tortfeasor who plants a banana tree on his or her neighbor's land without permission is liable for continuing trespass the entire time the banana tree remains on the land, even if the original tortfeasor never returns (*Thorton v. Schiavello*, 93 A.3d 656 (2014)). A trespass becomes permanent when the land is distorted or changed in a way that cannot be undone and is indefinite. Permanent trespass becomes possible in situations where water is diverted or dirt is removed. For example, a tortfeasor may create a permanent trespass when (s)he wrongfully and permanently diverts a natural creek away from an owner's property, destroying the soil and vegetation.

Trespass to Land is known as an intentional tort, meaning liability attaches if a person's *actions* have the purpose or substantial certainty of producing the result. This means that liability attaches if one's *actions* that led to the trespass were intentional, or if one's *actions* had the substantial certainty to lead to trespass. In other words, the trespass itself does not have to be intentional. It also means that one may be held liable for trespass even though there is no injury to the land or interest of the owner (i.e., damages do not need to be proven). In cases where the trespass was reckless, negligent, or the result of an abnormally dangerous activity, trespass only attaches if the person's or object's presence causes harm to the land, owner, or third party with a protected right.

In most jurisdictions in the United States, "no trespass" signs are not required to enforce civil trespass, even where local laws require "no trespass" signs be posted for the enforcement of criminal trespass.

The duty owed to protect a trespasser varies state by state. In Keegan v. Lemieux Security

Services Inc., a college security officer was patrolling Middlebury College in Vermont when she observed men entering a dangerous construction site on campus. The college had contracted with the construction agent to provide fencing and dedicated security services for the site due to the inherent construction dangers present. Although the site was within the college boarders, campus security was not responsible for patrolling it. College Security Officer Keegan entered the construction site to pursue a trespasser and was injured during the apprehension. In the state of Vermont, "a landowner or occupier generally owes no duty of care to a trespasser, except to avoid willful or wanton misconduct." Keegan sued the construction agent and its security service for negligence, claiming they owed a duty to protect her from injury. The Supreme Court of Vermont affirmed the trial court's decision dismissing the claim holding that "the defendants owed no greater duty to the officer than they owed to trespasser, and thus officer failed to show that defendants breached a duty owed to her, precluding recovery on a negligence claim" (*Keegan v. Lemieux Security Services, Inc.*, 177 Vt. 575, 861 A.2d 1135, (Vt. 2004)).

A tortfeasor's subjective reasoning for being on the trespassed property, adherence to good faith, and ignorance as to his/her current location ("mistake of fact") are not acceptable defenses to civil trespass. Many jurisdictions recognize "necessity" as a defense to trespass. Necessity allows someone to enter and remain on someone's land in an emergency situation in order to prevent hardship. For example, necessity allows someone to take emergency shelter from a storm without the fear of liability for trespass. (Necessity and emergency are a type of consent – see section VI on Defenses below.)

In Lebovitz v. Sheraton Operating Corporation, the plaintiff was physically removed from a hotel for alleged trespass after refusing to leave upon being asked to by hotel security. Plaintiff alleged he agreed to leave, but only after talking to a hotel manager. Without being allowed to talk to the manager, the plaintiff alleged he was physically dragged from the hotel and turned over to New Orleans Police where he was arrested and charged with criminal trespass. Hotel security claimed to police that he was removed from the hotel for ticket scalping, something the plaintiff denied. The hotel's motion for Summary Judgement was denied by both the trial court and the Court of Appeals of Louisiana, holding that "Even if the statute gives the hotel authority to ask persons to leave, it does not give it the authority to make false statements to the police leading to the persons' arrest" (*Lebovitz v. Sheraton Oper.*, 868 So. 2d 164 (La. Ct. App. 2004)).

Civil damages and legal remedies available for trespass to land include:

1. Nominal damages, i.e., a minimal amount of money is rewarded mainly to recognize that the plaintiff was wronged.
2. Compensatory damages to compensate the plaintiff for his/her injury and to make him/her whole. This includes actual damages, i.e., the actual monetary value of the damage, to compensate the plaintiff for damage to land or personal property that occurred during the trespass.
3. Putative damages, for which the sole purpose is to punish the trespasser.
4. Injunctive relief, being a stop order from the court, to prevent certain future conduct.

Easements

An action for trespass may not be maintained where the accused has an easement. An easement is the irrevocable right to use another's land for a specific purpose. In other words, easements allow for a person to go onto the land of another and make limited use of that property, such as for ingress or egress. There are two types of easements.

First is an easement appurtenant, which requires two parcels of land, usually adjoining. For example, a property owner who owns landlocked property (the dominant tenement) without access to any public roads may have an automatic easement allowing for him/her to travel over a neighbor's land (the servient tenement) to access his/her property. The dominant tenant has the right to enter onto the land of the servient tenant; the servient tenant is burdened by/subject to the easement. These easements may be automatic or

agreed upon by two individuals. These easements most often "run with the land," meaning they pass with the title to real property and cannot be revoked due to sale or rezoning of the property. However, if such an easement is no longer needed due to a change in the physical land (e.g., if a new road is built allowing access to the landlocked property), that easement can be vacated and no longer valid. Landowners that violate another's right to an easement may be liable for damages. For example, a landowner may not build a fence or a structure on his or her own property if it would interfere with a preexisting easement. In addition, a third party may not take advantage of an easement that (s)he is not part of.

The second type of easement is an easement in gross, involving one parcel of land and one servient tenement that is subject to the easement. For example, municipalities have the right to install a sewer line across a property's owner land to connect the house to the sewer system, and municipalities have the right to install telephone polls on one's front lawn. These easements are "personal" in nature and are intended to benefit the holder personally rather than a connection with any land that the owner may hold. Such an easement usually gives the easement holder a right to do something on another's land.

Interfering with a person's lawful easement over real property is not allowed, and a damaged party has several civil remedies at their disposal including asking the court for an injunction to stop the interference, bringing an action for nuisance or another tort, or damages if there is a loss.

Trespass Ab Initio

The doctrine of trespass ab initio is when one enters legally upon land in the exercise of a privilege properly conferred and subsequently abuses the privilege by a trespass to person, chattels, or land. The tortfeasor becomes liable not only for the later misconduct but also forfeits the original lawful entry to become a trespasser "ab initio" or from the beginning (75 Am Jur 2d Trespass §51).

When a property owner gives permission for someone to enter his or her land for business or commercial purposes, the property owner issues a license for the visitor to be on the property; the property owner is the "licensor" and the visitor is the "licensee." The license can be revoked or expire if the visitor remains on the land past the stated purpose (*State v. Zembreski*, 445 N.J. Super. 412 (2016)).

Those who visit another's land for personal reasons are classified by law as "invitees." An invitee who remains on the property to use it in the scope of his or her own interest and not for the purposes invited loses his or her status as an invitee and automatically becomes a trespasser (*State v. Girardier*, 484 S.W.3d 356 (2015)).

A licensee or invitee that properly enters land and commits a tortious act thereafter is responsible only for the tortious act and not trespass ab initio. However, if the entry to the land was fraudulent and only for the purpose of committing a tortious act, the tortfeasor can be held liable. Furthermore, in the event a licensee exceeds the authorized access granted in the license, does not conform with the license terms, or is otherwise revoked, the acts committed in excess of the licensee's authority may constitute trespass ab initio (*State v. Girardier*, 484 S.W.3d 356 (2015)).

Illustrative Example 1: Ashley the Assaulter is out with friends at a local movie theater. Ashley and her friends properly purchased tickets from the theater giving them the status of licensee. While waiting for the movie to start, Ashley observes an old rival, Victoria, walking into the theater. Ashley approaches and assaults Victoria during the opening credits. Since Ashley was at the theatre legally and with legitimate intent, Ashley is most likely not liable for trespass ab initio.

Illustrative Example 2: Ashley the Assaulter is angry at Victoria and wishes to find and harm her. Ashley is out driving around looking for Victoria when she hears from a friend that Victoria is at a local movie theater. Ashley buys a movie ticket for the sole purpose of going into the theater and assaulting Victoria, a plan she then carries out. Ashley is most likely liable for trespass ab initio for gaining access to the movie theater by purchasing a ticket and becoming a licensee, with fraudulent intent.

Security personnel and private investigators looking to gain access to another's land should be careful not to use depict or they risk accidently committing the tort of trespass ab initio.

Trespass to Chattel

The Restatement of Torts (Second) explains that a trespass to chattel (i.e., personal property) lies in interference to the rightful possession or enjoyment of its owner. A trespass to chattel is the intentional use of or interference with personal property, which is in the possession of another, without justification. It can occur when one dispossesses another of the chattel; "the chattel is impaired as to its condition, quality, or value; the possessor is deprived of the use of the chattel for a substantial time; bodily harm is caused to the possessor; or harm is caused to some person or thing in which the possessor has a legally protected interest" (*Restatement of the Law (Second), Torts §218*).

Trespass to chattels arises where a tortfeasor's actions or interference with another's chattels falls short of that required for a conversion. Some jurisdictions differentiate between Trespass to Chattel and Conversion based on the amount of damage done or whether a replacement chattel is required.

Defenses to Trespass

Defenses to trespass, of significance, include the following:

Infancy: Infancy (being under the age of majority) is not a defense to liability in trespass, although infancy may prohibit someone from being able to form the necessary intent to commit trespass.

Consent: In some jurisdictions, the plaintiff must prove a lack of consent. Consent need not be verbal; it can be contextual and determined through context. Local customs and rules can help determine consent. Emergencies or necessities can create consent (as noted above).

Reclaiming Chattel: In some cases, actors may be privileged to enter onto another's land to reclaim a chattel that was left behind. This may include a child, pet, or other chattel that has wandered onto the land of another. For example, some jurisdictions would support a person entering another's property to retrieve a hat that was blown off one's head by the wind.

Authority of Law: The law sometimes prescribes privilege as a matter of law for specific individuals to be able to access property under certain circumstances. This type of privilege often extends to utility workers and other government officials who may need access to property in emergency situations.

Public Access to Waterways: Most jurisdictions in the United States recognize public access to the inter-tidal zone of a beach or costal waterway. This allows people to walk along the water's edge regardless of who owns the adjacent property.

Private Nuisance: In some jurisdictions a landowner may enter an adjoining property without permission for the purpose of abating a condition that affects his/her land that constitutes a nuisance to the possessor's interest. A common example would be where landowner X does not visit his or her property often and a barn on X's property is broken into and used by local teenagers to host parties. X's neighbor is within his or her rights to enter onto X's property to board up the barn, preventing the teenagers from entering in the future. Examples of other types of supported abatement include trash removal and removal of a damaged tree.

Public Nuisance: A public safety officer may enter another's land, at a reasonable time and in a reasonable manner, for the purposes of abating a public nuisance (§ 202 Abatement of Public Nuisance by Public Official. Restat 2d of Torts, § 202).

Arrests: Government officials with arrest power for criminal offenses carry the privilege to enter another's land for the purpose of making an arrest.

Statute of Limitations: A statute of limitations is legislation that establishes the maximum time in which plaintiffs can bring an action after a tort or other offense has been committed. In most cases, the law prevents an injured party from taking legal action after a certain number of years after the

injury occurs or is discovered. Different civil wrongs have different prescribed time limitations. Not taking action on a permanent trespass, past the statute of limitations, may leave no possible remedies for the plaintiff.

Conversion

The Restatement of Torts (Second) defines conversion as an "intentional exercise of dominion or control over a chattel (personal property) of another, which so seriously interferes with the right of another to control it that the tortfeasor may justly be required to pay the owner the full value of the chattel" (*Restatement of the Law (Second), Torts §229*). As an "intentional tort," like trespass, only the tortfeasor's intent to control the chattel is necessary to find liability; the tortfeasor is not required to have the intent to dispossess the true owner of the chattel or even to know that the object belongs to another.

Today, English-speaking society colloquially refers to the tort of conversion as "theft." While there are some differences in the elements and relative intent, conversion is to civil law what theft/larceny is in criminal law. Theft/larceny is a criminal offense that is prosecuted by the state; conversion is a civil offense, where a complaint is brought forward in civil court by an injured party (the plaintiff).

Actions for conversion generally lie with respect to chattels; real property (i.e., real estate) is not subject to conversion.

In order for a plaintiff to successfully establish a claim for conversion, the following elements must be met: (1) the plaintiff had legal title to the converted property; (2) the plaintiff either had possession of the property or the right to possess it at the time of the conversion; (3) the defendant exercised dominion over the property in a manner which denied the plaintiff his/her rights to use and enjoy the property; (4) in those cases where the defendant lawfully, or at least without fault, obtained possession of the property, the plaintiff made some demand for the property's return which the defendant refused; and (5) the plaintiff has suffered damage by the loss of the property (*McTiernan v. Jellis*, 2013 WY 151, 316 P.3d 1153, 2013; Gould *v. Ochsner*, 2015 WY 101, 354 P.3d 965 (Wyo. 2015)).

A tortfeasor's intent or motives are irrelevant in determining liability for conversion, but may be relevant in determining damages (*Taylor v. Forte Hotels Int'l*, 235 Cal. App. 3d 1119 (1991)). In other words, it does not matter why someone converted the chattel in determining his or her guilt, but his or her intentions may mitigate or compound how much money he or she has to pay the plaintiff in damages. It is also important to point out that conversion does not require the tortfeasor to have exclusive control of the converted chattel (*Quantlab Techs. Ltd. v. Godlevsky*, 719 F. Supp. 2d 766 (2010)). This means that a chattel can be converted that is still in the possession of its owner, so long as the owner can no longer use the item for its intended purpose. An unauthorized use of an umbrella, later followed by a return of a broken umbrella (non-intentional), leaves the owner wet and unable to enjoy the benefit of his chattel. Similarly, a tortfeasor can be held liable for conversion for intentionally destroying or materially altering a chattel.

Even where someone has been given limited rights to use a chattel, a tortfeasor can be held liable for conversion for exceeding authorized use of a chattel if the rights of another who has the right to control the chattel are violated.

A chattel does not have to have monetary value for a plaintiff to sustain an action of conversion (*Palm Beach Golf Center-Boca, Inc. v. John G. Sarris*, D.D.S., P.A., 771 F.3d 1274 (2014)). Conversion can be attached to include documents "that embody an intangible right, such as stock certificates and bonds" (*Iglesias v. United States*, 848 F.2d 362 (1988)). However, an action for conversion cannot lie in a standard unpaid debt (*Geler v. National Westminster Bank,* 770 F. Supp. 210 (1991)) or "where damages are merely being sought for breach of contract" (*Peters Griffin Woodward, Inc. v. WCSC, Inc.*, 88 A.D.2d 883, 452 N.Y.S.2d 599 (1982)).

Intellectual property such as poems and songs cannot be the subject of an action for conversion, unless they were reduced to a physical form and that physical form was converted (*Quantlab*

Techs. Ltd. (BVI) v. Godlevsky, 719 F. Supp. 2d 766 (2010)). Therefore, it would not be conversion to hand copy a written work onto a medium that one already owns. However, it would be conversion to use someone else's parchment to handwrite a poem.

Conversion deprives the rightful owner or user of the property permanently or for an indefinite time. Depriving an owner or user of his or her property for a short, finite time with the intention to return the property may not qualify as conversion (*Macomber v. Travelers Prop. & Cas. Corp.*, 261 Conn. 620 (2002)) (although it may qualify as trespass to chattels; see above). In cases where the defendant first legally borrowed the chattel in question, the plaintiff must make a demand for the property's return, with a refusal to deliver, before liability for conversion attaches. In many jurisdictions, this is true even where the borrower retains the chattel past an agreed-upon return date.

Illustrative Example 1: Boris the Borrower "borrows" his neighbor's lawn mower for 5 weeks straight; Boris took the lawn mower from his neighbor's shed without permission. Boris returns the lawn mower in the same condition he found it, with a full tank of fuel, and before the owner attempted to use it or noticed it missing. Boris the Borrower is most likely not liable for conversion. Boris the Borrower may be guilty of trespass (see trespass above).

Illustrative Example 2: Boris the Borrower "borrows" his neighbor's lawn mower for 5 straight weeks; Boris took the lawn mower from his neighbor's shed without permission. Boris returns the lawn mower in the same condition he found it, with a full tank of fuel. However, while it was missing, rightful owner went to use the lawnmower, noticed it was missing, and purchased a replacement. Boris the Borrower is most likely liable for conversion (and possible trespass; see above) and would be responsible for paying damages.

Damages for Conversion

The law generally allows the injured party to either recover the chattel, seek damages, or both.

When it comes to paying monetary damages for conversion, what standards should the courts apply? Should the tortfeasor pay the original cost the owner paid for the chattel? The present value of the chattel at the time converted? The cost of replacing the chattel? What if the tortfeasor sold the chattel at a significant profit? Being that items may appreciate or depreciate in value over time, these questions are not simple.

The Restatement of Torts (Second) provides general guidance for how much a tortfeasor should pay in damages:

> In determining the seriousness of the interference and the justice of requiring the actor to pay the full value, the following factors are important: (a) the extent and duration of the actor's exercise of dominion or control; (b) the actor's intent to assert a right in fact inconsistent with the other's right of control; (c) the actor's good faith; (d) the extent and duration of the resulting interference with the other's right of control; (e) the harm done to the chattel; and (f) the inconvenience and expense caused to the other. (*Restatement of the Law (Second), Torts §222A*)

In other words, the court will examine the motives and actions of the tortfeasor, taking into account how long and to what extent the tortfeasor's actions deprived the plaintiff to access and rightful enjoyment of his or her chattel. The court will also examine the actual damages or inconvenience to the plaintiff.

Conclusion

Modern tort law has been shaped by almost four thousand years of political, economic, and social trends. The United States has a complex system of civil-based tort law that protects property interests and provides prescribed remedies when damage or injury to property occurs. It is difficult to predict the future of tort law. While tort reform was a significant topic in the latter half of the twentieth century, much talk of major reform has been replaced by tinkering at both the national and state level to make the system more efficient and user friendly for litigants.

Workplace: Hostile Environment

Emily Schindeler
Griffith Criminology Institute, Griffith University, Brisbane, QLD, Australia

Keywords
Workplace hostilities · Harassment · Prevalence · Risk · Prevention

Definition

Hostility within the workplace is an umbrella term encompassing behaviors – including harassment, aggression, bullying, emotional and verbal abuse, anti-social behavior, incivility, or abusive supervision – that cause harm to a target as well as to bystanders. In the United States workplace hostility refers specifically to prohibited discriminatory behaviors as administered by the federal Equal Employment Opportunity Commission (EEOC) and set out in civil rights legislation. This is paralleled in the *United Kingdom Equality Act 2010*. Injurious behaviors and targets not falling within the ambit of the legal protections in the anti-discrimination legislation are included in other national jurisdictions such as the *Workplace Health and Safety Act 2011* in Australia.

Introduction

The classification of abusive behaviors within the work environment has been debated by academic researchers, organizational behaviorists, regulators, national and state governments, the European Union, the International Labor Organization, and the World Health Organization. A useful illustration is found in Neall and Tuckey's (2014) review of 234 peer reviewed articles which found 36% adopted workplace bullying, 21.3% workplace aggression, 10% workplace harassment, and 9.2% workplace incivility and abusive supervision each. Irrespective of differences in characterizations, there are commonalities in that behaviors involve intent to do harm, identification of a specific target or targets, and the presence of severe and recurring acts. Protections are grounded in definitions of harm rather than simple offense (PLC Labor & Employment 2014). It is important to recognize that persistent incivility and environmental toxicity (rendering the individual socially isolated and devalued) can lead to the same harm that is ascribed to more aggressive forms of harassment.

However, the nature of terminology has critical repercussions for who may be protected, who is responsible, and under what conditions. Definitions embedded in statutory protections and regulations proscribe specific behaviors and actions, potential reparations for victims, as well as responsibilities of employers.

For example, by limiting the definition of harassment to a protected characteristic the focus is directed to the individual trait as the basis for the abusive action itself. This demonstrates how the process of definition and consequent parameter setting can result in discrimination against particular victims or protect particular offenders. There is a specific consequence of the specifications adopted in legislation and the locus of responsibility for enforcement. It is in this context that the EEOC Taskforce (2016) did not limit their investigation into harassment to a legal definition recognizing that conduct which is not specifically illegal can create an environment in which unlawful hostilities can occur. Outside of the United States, protections against abusive behavior which causes psychological harm are found in labor laws as well as workplace health and safety laws and regulations (e.g., France, Australia, and Canada).

Conduct characteristic of hostility in the workplace sits apart from physical assault which is illegal under criminal law. In the United States, conduct subject to EEOC protections involve discrimination against the individual(s) target based upon age, race, religion, sex, national origin, or disability. Legal requirements demand that discrimination must be ongoing over time; involve behavior that a reasonable person would find intimidating, hostile, and abusive; and evidence that such treatment interferes with the individual's ability to work and career advancement. Further, the target is required to report to the employer of the complaint. The employer then becomes liable for any failure for inadequately intervening. Retaliatory discrimination against a person who has filed a charge of discrimination or been involved in investigation or testifying in such cases is also unlawful. The U. S. Occupational Safety and Health Administration has an interest in the protection of workers but limited regulatory or enforcement powers specific to workplace hostilities as compared with physical violence (https://www.osha.gov/SLTC/workplaceviolence/standards.html). Accordingly, while federal protections are provided for a target having a specified attribute, a victim who is not captured by the civil rights provisions has significantly diminished protection.

Abuse consistent with definitions of hostility in the work environment may be perpetrated by those in positions of authority, peers, or subordinates. Individuals or groups of individuals may be involved as perpetrators and victims may include not only the target but also bystanders. As noted by Reynald (2016), bystanders are inclusive of those who witness victimization and those who are in receipt of official reporting within the organization and regulators responsible for action. Bystanders may become secondary victims as well as having a potential capacity to act as an intervener. Those factors that may inhibit victim's reporting are equally applicable to the bystander. These include a fear of becoming a target, lack of confidence that management would be supportive or take action, unsure whether co-workers would support the action and concern for the lack of personal protection against risks (Wortley 2015). Perceived seriousness of the behavior, closeness to the target, and perceived personal responsibility to act will also influence bystander responses. An organizational culture which accepts if not condones such mistreatment is also a powerful inhibitor to action being taken (Pershing 2003; D'Cruz and Noronha 2010). While legislated protections focus on those employed by an organization, abuse may also emanate from third parties such as clients, patients, and consumers and which is not covered by legislated protections.

Prevalence

Determining the prevalence of workplace hostilities is fraught by confounding factors. Under-reporting may be a consequence of a victim's fear of taking action given the employment risks, victims may elect to leave the workplace to escape the situation, and victims may simply be unaware of their rights (Schindeler 2016). National, industry specific and specialist prevalence studies have adopted selected definitions, collection, and measurement tools. Methodologies have ranged from those based on unfettered self-reporting of experiences perceived as hostile, reporting according to

specific (but often different) criteria, applying measurement tools based on behavioral characteristics, and/or consequences. For this reason, it is not possible to produce comparative studies given the lack of consistency in definitions, criteria, and methodology. Acknowledging these limitations, recording a small number of prevalence studies is useful in demonstrating the relevance of the problem.

Recognizing the need for greater attention to workplace mistreatment, the National Institute for Occupational Safety (NIOSH) and Health and the Centres for Disease Control and Prevention (CDC) initiated the inclusion of relevant questions in the 2010 *National Survey of Workplace Mistreatment and Absenteeism* (Asfaw et al. 2014). Some 13,000 respondents to the National Health Interview Survey were asked, "During the past 12 months, were you threatened, bullied, or harassed by anyone while you were on the job?" The responses to this question revealed that 7.6% of US workers employed at the time of the survey (2010) had been mistreated at their workplace. Some five years later, the EEOC *Select Task Force on the Study of Harassment in the Workplace* (Feldblum and Lipnic 2016) reported that an allegation of harassment accounted for nearly one third of the 90,000 employment discrimination charges received by the EEOC in 2015. These two studies approached understanding prevalence from different perspectives and therefore cannot be directly equated. For example, the Task Force was able to look at formal complaints of discrimination as well as drawing on complementary studies as compared to the single NIOSH and CDC survey. Examining incidence based upon the employment sectors, the Task Force found that allegations of harassment centered on sex and race were most prevalent in the private sector, accounting for 45% and 34% of charges, respectively. In contrast, allegations of harassment based on race and disability were most prominent in the public sector, accounting for 36% and 34% charges, respectively.

A corollary to being a direct target of hostility is the need to recognize the flow on impact on bystanders. In the Danish national cohort study set out in *Working Environment and Health in Denmark 2012–2020* (Nielsen and Moller 2012) and the *Finnish Quality of Work Life Survey* (OSF 2008) that the proportion of respondents witnessing hostile behaviors increased greater than the number reporting victims of such abuse. These studies reported that bystanders experienced similar levels of psychological harm as a consequence of witnessing the mistreatment to others. This can result in health impacts of increased stress, in the need to change workplaces completely, as well as emotional distress. There are consequential flow on costs to the organization and productivity.

Environmental Risk Factors

Two theoretical positions are linked to risk factors as the principle causes of hostilities within the workplace and the types of preventative and intervention strategies that are often promoted. The first locates the source of hostilities as grounded in inter-personal conflict which can be addressed through strategies designed to prevent or respond to such clashes. The abusive supervisor or workplace psychopaths are expressions of this thinking. The alternative explanation views workplace is a result of cultural and systemic factors inherent in the organisation. Recognizing that environmental conditions can be conducive to individual behaviors; these two explanatory frameworks are not mutually exclusive (Eurofound 2015). The relationship between organizational culture and individual factors is brought together by Sallin (2003). In this model, enabling and motivating structures or inducements and specific events interact creating the ideal conditions for workplace hostilities. This also indicates that prevention and intervention techniques need to be tailored to organizational environments, at different levels and with different characteristics.

Internal organizational factors which may increase the potential for hostility in the workplace involve a combination of influences within the ability to be mediated by the employing organization. Any or all of these organizational characteristics may intensify the level of risk of

unacceptable and harmful inter-personal behaviors. Management styles will set the overall organizational culture. Autocratic leadership styles, lack of accountability for decision–making, and promotion of a divisive work culture are all risk factors (Hoel et al. 2010; Ferris et al. 2007). Poor leadership may generate risk in the form of system failures. System failures may include providing inadequate resources, making unreasonable performance demands, failing to provide adequate support, and poor communication. Broadly categorized as work-related factors linked to risk include tolerance of unreasonable behavior, job insecurity, role conflict, and ambiguity, as well as organizational change.

The manner by which managerial practices are implemented such as performance assessment, performance management, the provision of incentives, and a lack of disincentives will impact on the perception of fairness. When processes are viewed as unreliable or unfair, they become a risk factor for harm. Performance appraisal and management have been promoted as a constructive way of addressing problems in productivity or quality of work. At the same time, these processes have been associated with claims of abuse – that is the process has been used as tactic for victimizing individuals and harm-inducing. As a reflection of the organizational climate, the application of management practices may be effectively abusive or supportive. Organizational practices which reinforce abusive behaviors by providing justifications enable such practices to persist (Piquero 2005).

Failure of the organization to provide credible responses to complaints is a significant risk factor. Supervisors or managers and human resource staff failure to deal with complaints, which adopt an approach that blames the victim or that is tacitly supportive of the accused can lead to an actual increase in workplace hostilities. Where implementation of policies and procedures is perceived as ineffective and those responsible for taking action are not trusted, there is reduced likelihood that victims or bystanders will report the offending behavior (Reynald 2016; Wortley 2015). Observing how an organization responds to victims of workplace hostilities may communicate that such abuse is "part of the job," intensify the stressors and increase the nature of risk (Hoobler and Swanberg 2006).

The climate which emerges from the interaction of organizational power and politics produces environments conducive to workplace hostilities, culminating in a form of systemic abuse. This can have the profound impact on normalizing what is harmful even if not illegal behavior (Leiter and Patterson 2014).

Prevention and Intervention

There is no single recipe which will ensure protection against workplace hostilities. There are pre-requisites without which prevention is unlikely to be successful. For example, policies and procedures that address specific behaviors in isolation are inadequate. There is a need for an organizational culture, ethical framework, and accountable, reliable systems to reduce the risk of workplace hostilities. Similarly the EEOC Special Task Force (Feldblum and Lipnic 2016) identified a number of workplace characteristics that are linked to risk and for which particular responses are suggested. For example, homogeneity and diversity of workplaces and the evidence of specific vulnerable groups are identified among risk factors. Effective prevention requires leadership to convey the values and ethics of the organization, in both the private and public sectors.

The processes associated with risk assessment and development of prevention and intervention strategies need to be inclusive. This requires the involvement of both management and those working at the ground level. Effective prevention demands ongoing monitoring to identify emerging risks and a willingness to take remedial action. For example, the emergence of social media as a site for targeted abuse represents an emerging risk for which online training programs are accessible, primarily through the private sector providers. However, there has not been any robust evaluation of their effectiveness. Evaluation of the effectiveness of prevention and intervention actions similarly needs to be inclusive, form part

of the monitoring process and strategies focused on cultural change. An over-reliance on complaints is an insufficient measure of the effectiveness of strategies given the imposts to victim or bystander complaints.

The features of any intervention must be tailored to respond at least one or more risks. Primary interventions are preventative and are primarily organization-focused. Awareness raising activities, leadership development, and identifying systemic factors contributing to risk fall within this category of intervention (Vartia and Leka 2011). For example, leadership development approaches focusing on enhancing the quality or culture of the work environment are potentially influential in reducing risk even when workplace hostilities may not be the ostensible goal. Risk may also be reduced when action is taken to reduce work-related stress through work design, organizational practices, and improve communication even where not positioned from the perspective of reducing hostilities (Ng et al. 2014).

Secondary interventions are intended to improve responses to identified risks. This includes such actions as promoting behavioral change and individual resilience as related to group dynamics. Improving internal processes, including the operation of human resource management practices, are included in this level. Interventions involving the adoption of risk assessment tools and providing coal face training including involving interpersonal skill development have promoted as options. However, there is a paucity of evaluations that have demonstrated sustainable outcomes for such initiatives (Hoel and Giga 2006; Hodgins et al. (2014); Evesson and Oxenbridge 2015).

Tertiary interventions must provide effective outcomes for victims as well as appropriate responses to perpetrators. Both organizational wide and targeted approaches must address context relevant risk factors. Repairing the harm after the fact requires attention to recovery for individuals and work groups. This includes providing remediation for the victims (including bystanders impacted while not the direct target) as well as addressing the risks which enabled the offending to occur. Critically, the events which led to the abuse and identification of the factors that enabled it to occur are then able to be employed in reviewing the organization's prevention strategies (US Merit Systems Protection Board 2012; Safe Work Australia 2013).

An alternative framework is to categorize the nature of actions being taken as organizational, administrative, or behavioral. Organizational and administrative actions may include, for example, adoption of relevant policies and procedures, developing programs, or addressing ways to improve work management systems. Behavioral focused actions may include for example awareness raising campaigns, interpersonal skill development (e.g., managing aggression or conflict management), or communication skills.

Codes of practice, guidelines, and advisory notes provide common processes or approaches to assist organizations to development strategies for prevention and intervention (Safe Work Australia 2013; Department for Business Innovation and Skills 2009; US Merit System Protection Board 2012). Elements which are commonly included are engagement, risk assessment, controlling of risks, and responding to incidents. Engagement provides the means by which critical environmental factors are able to be identified and advise locally appropriate responses. Risk-assessment tools direct consideration to potential work-related stressors, systemic problems, and management styles. Monitoring patterns of absenteeism, sick leave, and complaints provide additional data indicating risk. Controlling of risks then can be directed towards those elements which have been identified as problematic. Finally processes for responding to incidents and complaints which provide remedial action and recovery are the critical components of the overall prevention strategy.

Conclusion

There are significant gaps in research that require attention. The problem of investigating claims, the problem of evidence, and the responsibility of victims to produce "credible evidence"

remain problematic as does the transparency of decision-making. Greater clarity as to what constitutes evidence and how it will be collected and assessed is needed for victims, bystanders, investigators, and managers. An accountable investigatory and decision-making process which establishes greater clarity of responsibility is needed. This gap includes limited evidence of the effectiveness of approaches that focus not on the victim but on the perpetrators. There is a paucity of robust evidence of the long-term effectiveness of any of the interventions that are widely promoted, particularly in organizations that have prior experience with workplace hostility problems. This will necessitate a continuing focus and collaborative approach with employers and regulators to test and document the quality and sustainability of actions.

Privacy · Workplace · Expectation of privacy · Search · Probable cause · Reasonable · Employee monitoring · Surveillance · Risk

Definition

Privacy in the workplace refers to an employee's presumptive right to limited privacy including use of the organization's phones, computers, desks, lockers, and other equipment, in accordance with that organization's legal rules and policies.

Introduction

This article discusses privacy in the workplace and the privacy protections of the 4th Amendment to the US Constitution.

Privacy is an assumed right that is not implicitly mentioned in the US Constitution. It can be inferred from several sections of the constitution, most notably the 4th Amendment. A number of US Supreme Court cases support this. The 4th Amendment states that:

> The right of the people to be secure in their persons, houses, papers, and effects, against unreasonable searches and seizures, shall not be violated, and no Warrants shall issue, but upon probable cause, supported by Oath or affirmation, and particularly describing the place to be searched, and the persons or things to be seized (Cornell Legal Information Institute (2) n.d.)

Privacy Rights and Limitations in the Workplace

Limitations

Privacy rights are protected by federal and state laws, as well as regulations. These rights exist in the workplace but are limited. Cooper (2012) expresses this idea by stating that "Americans have as citizens enjoyed certain rights that they are required to leave behind when they enter the doors of the organizations in which they work." These rights are, most notably, "freedom of speech, press, and assembly; due process of law; privacy; and freedom of conscience," and, to the point, "most Americans are not guaranteed these rights in the workplace" (Cooper 2012)

Expectation of Privacy

Employees generally enjoy a reasonable expectation of privacy on the workplace, but the word

"reasonable" requires some definition (Justia n.d.). Legally, the concept is based on what would be reasonable under certain circumstances that would otherwise be considered unusual or require a warrant issued by a court for intervention (Justia n.d.).

The general principal is that searches of an employee's workspace, or of equipment and technology used by the employee, are justified only under certain circumstances. Managers and supervisors have limited rights to search employee occupied areas or organizational equipment employees use. These would include physical spaces such as desks and lockers, and technology such as computers, email, and phones. Any searches of areas used personally by employees must be for valid reasons, either for probable cause (a high evidentiary standard) or reasons that fall under the organization's policies. This usually requires prior notice to the employees unless there is substantive evidence of fraud or wrongdoing by that employee, or the employee has given consent. Reasonableness also does not usually require a warrant for searches whose purpose is to obtain job-relevant material (Berman et al. 2016).

The expectation of privacy is a pervasive issue as employees generally seek a level of comfort in the workplace and do not wish to have their job spaces intruded upon. Exceptions to this would be secure areas in government and research where closer scrutiny is part of the culture. In general, however, the human resources department must ensure that the "need for the monitoring is supported by a legitimate business justification and that employees understand they have no reasonable expectation of privacy when they are using employer-provided equipment and systems" (Society for Human Resource Management n.d.). Thus, the human resources strategy is to provide a personnel comfort level with searches by ensuring that reasonable notice of searches is given.

Legal Issues

Overview

The 4th amendment protects against illegal search and seizure. In the workplace this is problematic as there is a conflict between employer rights to control the organization's property and the limited privacy rights of the employee. The right to privacy in the workplace continues to be controversial as employers can control an employee's workspace and the employee's means of communication (Berman et al. 2016, p. 119). The additional complicating factor here is the employer's technology, which is used by the employee but controlled by the employer.

The employer's property rights further conflict with the employees' privacy rights when organizational communications are checked, thus while monitoring an employee's communication may impinge on his or her privacy the employer may engage in such activity as long as the employee are given notice (Berman et al. 2016, p. 119). This practice may also include private conversations in employer owned spaces. Workspaces such as desks and lockers may be considered more controversial as the expectation of privacy may be greater in those areas despite court cases favoring the employer (O'Connor v. Ortega 1987). Testing for drug use is also a point of concern unless prior consent is obtained or probable cause of crime exists (Society for Human Resource Management n.d.).

Disgruntled employees who feel their rights have been violated can bring actions against employers. Lawsuits and claims can be costly and time consuming. Employers might spend valuable resources and managerial time defending against such actions. Employee relations can worsen and the employers may also suffer reputational damage from negative publicity. Adverse information obtained by employee monitoring can also lead to discipline, termination, or loss of money and benefits. These consequences are burdensome, cost time and money, and must be calculated when forming policies and engaging in monitoring activities.

Relevant Cases

There are numerous cases involving employees' privacy rights and limitations in the workplace. In the US Supreme Court case O'Connor v. Ortega (1987), the issue of searches in an employee's desk was decided. "Conflicts arise when people feel that managers invade their private affairs or private workspaces," as problems occur when the

search is unreasonable (Berman et al. 2016), p. 2018. Employers are restricted from such "unreasonable" searches where the employee has a "reasonable expectation of privacy" in such areas as desks, lockers, and file cabinets (Berman et al. 2016, p. 118).

But employees do not have the same privacy rights when using company email systems, even if such communications are usually considered privileged, as decided in US v. Hamilton (EPIC.org n.d.). In this case, the Court decided that the employer's (in this case the government's) right to access emails outweighed the employee's privacy interests.

Probable cause (a high standard of evidence) was superseded by the "reasonable suspicion" standard in the 1968 US Supreme Court case of Terry v. Ohio (Cornell Legal Information Institute (3) n.d.). This premise applies to places of business as well as homes and public places (Cornell Legal Information Institute (3) n.d.). Reasonable suspicion is a concept the Supreme Court judged as necessary to enable law enforcement to determine if searches were justifiable under certain conditions. A police officer may act if he or she reasonably suspects someone has committed or is about to commit a crime. The extension of this principle in the workplace is that an employer does not need probable cause to conduct a search of an employees' desk or emails if justifiable policy allows it or exigent circumstances exist. The specific situational factors determine the viability of the employer's search (EPIC.org n.d.).

The reasonable expectation of privacy issue was addressed in Katz v. US (1967) in which the US Supreme Court provided further substantiation of the legal parameters for a search and an employee's right to privacy. The Katz ruling updated and amended the judgments of previous court cases and extended privacy protections "to all areas where a person has a reasonable expectation of privacy" (Tokson 2016). For example, the court determined that "immaterial intrusion" involving technology would now be considered a search (Tokson 2016). This case provides what is known as the two-part Katz Test, which says that "first is that the plaintiff displayed an expectation of privacy" and then that "the second is that this expectation is 'reasonable'" (Tokson 2016). This test may apply to the workplace.

Searches – Consent

Employee consent to a search can be implied or in writing. However, implied consent applies when "surrounding circumstances exist that would lead a reasonable person to believe that this consent had been given, although no direct, express, or explicit words of agreement had been uttered" (Cornell Legal Information Institute (1) n.d.). Written consent must be in a form that would prove valid in a court of law. When an employee consents to a search or to provide personal information, then the right to privacy has been waived.

Organization policies on the use of office space, furniture, communications, and equipment is usually in writing, and often employees must sign a document indicating they understand, and consent to, such policies. In those cases, the employees' rights to privacy is usually considered waived. Further, if the employee signed an agreement upon employment allowing the employer to search employee occupied areas, or the employee's emails or phone records, or take and use photos or images of the employees, then consent in those circumstance is again usually considered waived as well.

However, in the case of government employees, the "employer's control of the premises and the equipment, the implied consent of the worker who is generally informed that monitoring might take place. . .. . .combine to greatly limit a government employee's reasonable expectation of privacy" (Rothstein 2000).

HIPAA

The Health Information Portability and Accountability Act of 1996 (HIPAA) provides that employees' health information must be kept confidential by an employer. "The Privacy Rule, a Federal law, gives you rights over your health information and sets rules and limits on who can look at and receive your health information" and thus provides a layer of protection for employees (US Department of Health and Human Services n.d.). Further "the Privacy Rule applies to all forms of individuals' protected health information, whether electronic, written, or oral" and

"the Security Rule is a Federal law that requires security for health information in electronic form" (US Department of Health and Human Services n.d.). Therefore, there are strong regulations that safeguard personnel medical information, and usually human resources departments are responsible for this. This is especially true for medical insurance files and claims by employees. These regulations restrict access by third parties without good cause or a court order (US Department of Health and Human Services n.d.).

Workplace Privacy – Physical

Office Spaces, Desks, and Lockers

These assets are assigned by the employer to specific employees, as differentiated from to public areas and equipment for use by many, or all. As mentioned above, the privacy rights for these employer-owned items are often assumed by employees or equipment is used without consideration of consequences. People in offices typically do not think about their private or personal use of these items. Employer searches of these areas, absent specific consent or notice, can therefore cause resentment, complaints, or claims and lawsuits. This is undoubtedly more of an issue if the employee has been working in that organization for a longer period of time. Privacy rights are usually not a concern until a worker is confronted with a search (Katz v. US 1967).

Drug Testing

Drug testing is often a controversial intrusion into an employee's job. Such testing is sometimes required at hiring as a condition of employment, and often used randomly to see if staff is engaging in illegal use of controlled substances. The general premise is that "an employer may be able to require its employees to submit to drug screening" (Society for Human Resource Management n.d.). Written consent is required, unless there is probable cause, for example, discovery of drugs or drug paraphernalia or knowledge of "workers whom management believe have been using drugs based on physical evidence or behavior" such as glassy eyes or slurred speech. (Society for Human Resource Management n.d.). This testing is typically the responsibility of human resources. There are issues with random testing as some employees may feel targeted, resulting in disparate treatment claims (i.e., being treated differently for illegal reasons) (Nolo.com n.d.). There are also practical issues as to how and when the testing would be done, and the custody and control of the evidence. Most drug tests as of this writing are saliva tests (which are less problematic than urine tests) and can be done on premises.

Workplace Privacy – Technology

An employee's privacy has become more problematic as "the increased use of technology in the workplace has created new concerns for both employers and employees in the area of privacy" (Beekman Center for Internet and Privacy n.d.). Employers own or control the technology used by the employees in the workplace, which includes the Internet, cameras, voicemail, telephones, email, computers (desktops, laptops, tablets), cell phones, office phones, and other electronic communications.

Computers

Employees use equipment such as computers and PDAs (Personal Digital Assistants) that belong to the employer. While they have permission to use such equipment, they do not own it, and their use of it is therefore subject to the rules of the employer. Personal use of this equipment may be allowed but may subject to employer scrutiny. Here is where the grey area exists and the risk of conflict increases.

Documents and data on these devices may be the product of the employee but is generally considered to be owned by the employer, even if such data is of a personal nature. Employer systems are subject to the owner's property rights which typically supersede any privacy rights presumptions (Skok 1999). Thus, the employees' privacy rights may be diminished.

Internet Usage, Clickstream Data, and Email

Emails and data sent through the employer's "electronic information network" is generally considered to be the employer's property (Society for Human Resource Management n.d.). However, "once an expectation of privacy is established in clickstream data" Fourth Amendment protections involving "the reasonableness of searches and seizures" readily attach (Skok 1999).

Workplace users of clickstream data on the Internet are subject to employer intrusion, despite a reasonable expectation of privacy of the employee (Skok 1999). While such intrusions, or searches, must be reasonable and mindful of an individual's Fourth Amendment rights, the employer can argue a compelling interest despite protection of the courts against such "overly extensive and indiscriminate intrusion into our online lives" (Skok 1999). Employer systems can check emails with little impunity as employee suits "have not enjoyed much success" (Society for Human Resource Management n.d.). In addition, employer's use of such data is problematic as such employers must be "mindful of the discoverability of electronic communications" (Society for Human Resource Management n.d.).

Phone Calls and Voice Messages

The same is true for phone calls as employers may monitor such communications if there is a compelling need, the employee is given notice, or probable cause exists (Berman et al. 2016). Employers have access to voice messages collected and stored by the employee as well, but such monitoring is still the subject of controversy.

Employee Monitoring

Employers may have legitimate and compelling reasons for collecting information about their employees such as "guarding trade secrets," "monitoring for performance indicators," and bad behavior, risk management issues and evidence of prior illegal acts (Beekman Center for Internet and Privacy n.d.). The interest of the organization is served when "data about employee performance, for instance, can be used for better planning and resource allocation" or where more employee training is necessary.

(Beekman Center for Internet and Privacy n.d.). However, this "information could unnecessarily damage an employee's reputation with an employer or cause unneeded suspicion" and distrust, and this is one of several issues where the legitimate violation of an employee's privacy can cause more harm than good (Beekman Center for Internet and Privacy n.d.). Data obtained by employee surveillance is another problem-laden issue, and even if for internal use, this method of information collection may carry significant risk (Beekman Center for Internet and Privacy n.d.).

The liability created by employee monitoring is potentially costly as "conflicts arise when people feel that managers invade their private affairs or private workspaces". Trust is an important element in employee relations and may be compromised as employee monitoring changes the equation between the organization and its workers by "questioning employee rights to privacy, autonomy, and respect". Organizations may use electronic monitoring technology such as surveillance cameras usually without notice to employees if used in public places (bathrooms are not allowed), as there is no reasonable expectation of privacy in such spaces. However, the practical issues of employee resentment, lawsuits and claims, and turnover, put stress on human resources departments. Employers therefore need a reasoned approach to search and monitoring policies.

Employers may use technology to manage their exposures "to prevent injuries, misconduct and other types of loss" (Society for Human Resource Management n.d.). Organizations may also be concerned by business risks and threats, despite privacy concerns, and may then decide "to track all employee e-mail, Internet and telephone use without employees even knowing that they are being monitored" (Society for Human Resource Management n.d.). In many of these cases, employers must heed laws requiring notice

of monitoring as privacy rights may be affected, and legally advising employees of such surveillance is the most prudent course (Society for Human Resource Management n.d.).

Further, employers may monitor phone calls and access voice mail as part of normal course of business but not without good reason (Society for Human Resource Management n.d.). Employers also have the right to track and manage employees' use of the organization's Internet (Berman et al. 2016). Many of these interactions fall under the Electronics Communications Privacy Act (ECPA) which limits the employers ability to intrude in workers phone conversations. For example, an organization usually cannot engage in surveillance of employee's telephone usage, even if on the organization's equipment (Society for Human Resource Management n.d.). To complicate matters, the ECPA protects the employee's privacy in the use of such technology as, generally, the employer is at risk as the law "generally prohibits unauthorized and intentional 'interception' of wire, oral, and electronic communications. . ." (Beekman Center for Internet and Privacy n.d.). The ECPA additionally guards employee rights as it basically precludes "unauthorized 'accessing' of electronically stored wire or electronic communications" (Cornell Legal Information Institute (1) n.d.). However, the ECPA includes a number of exceptions to these rules including the "*business purpose exception*, which permits employers to monitor oral and electronic communications as long as the company can show a legitimate business purpose for doing so" (Society for Human Resource Management n.d.). Another is the *"consent exception" wherein an employee provides the employer with consent for such monitoring* (Society for Human Resource Management n.d.).

Analysis and Conclusion

Privacy as a practical matter is based more on transactional elements than philosophical legal notions. However, the risk and liability of searches and employee monitoring are significant and must be mitigated by well-considered policy and sound legal advice. "Overall, the majority of employers monitor the activities of their subordinates in some form, and clandestine observation is widespread". However, given the advances in technology, the temptation for employers is to increase surveillance and information collection thus mitigating the employees' rights to privacy while increasing the risks for the employer. This presents challenges for employers and employees alike, and the struggle for balancing the needs of both will continue into the future until the courts can shed more light on this very grey area.

Workplace: Sexual Harassment

Duygu Biricik Gulseren and E. Kevin Kelloway
Department of Psychology, Saint Mary's University, Halifax, NS, Canada

Keywords
Workplace sexual harassment · Gender harassment · Sexual coercion · Workplace aggression

Definition

Workplace sexual harassment is a type of workplace aggression that is defined as "conduct as unwanted or unwelcome, and which has purpose or effect of being intimidating, hostile, degrading, humiliating or offensive" (McDonald 2012, p. 14).

Introduction

The phenomenon of workplace sexual harassment was first identified as an occupational problem in the 1970s, and it has received a great deal of attention from researchers, practitioners, and the media ever since. Although there has been a decrease in the number of formal complaints of workplace sexual harassment in the last decade (Quick and McFadyen 2017), it continues to be a significant problem for both organizations and individuals. Victims of workplace sexual harassment suffer from a wide range of mental health problems that are difficult to treat. Similarly, organizations face a significant amount of productivity loss on top of costs associated with litigation and human rights complaints.

There are at least three approaches to defining workplace sexual harassment: (1) legal, (2) sociopsychological, and (3) public (Cortina and Berdahl 2008). The legal definition of workplace sexual harassment may differ depending on the legislative jurisdiction. For example, the Equal Employment Opportunity Commission's definition recognizes unwanted sexual conduct as workplace sexual harassment if it results in negative work outcomes, such as decreased performance (Quick and McFadyen 2017). The sociopsychological definition of workplace sexual harassment relies on targets' perception of behaviors regardless of the outcomes. Finally, the public definition of workplace sexual harassment is less precise and typically focuses on conduct that is generally accepted as sexually offensive by the public. Workplace sexual harassment behaviors can be categorized in three major groups: (1) gender harassment (e.g., misogynistic comments), (2) unwanted sexual attention (e.g., unwanted physical contact or sexual comments), and (3) sexual coercion or quid pro quo (e.g., asking for sexual favors in exchange for an organizational resource or decision) (Fitzgerald et al. 1997).

About 50% of women and 30% of men were estimated to be victims of workplace sexual harassment in the American workforce (McLaughlin et al. 2012). The comparable figures are much smaller in Scandinavian countries (i.e., a total of 2% of working women in Sweden and 11% of working women in Denmark have been victims of workplace sexual harassment) (Timmerman and Bajema 1999); but much higher in Austria (i.e., workplace sexual harassment victims make up 80% of all women workers in the workforce) (Timmerman and Bajema 1999) than the American statistics. Sexual harassment is a more common problem in gender-imbalanced industries, such as military or healthcare. For example, Estrada and Berggren (2009) found that 84% of the female cadets from a sample of Swedish military personnel experienced at least one episode of workplace sexual harassment within the last 2 years of the study. Working for the military is a risk factor of sexual harassment for men as well. Evidence shows that men are ten times more likely to be exposed to workplace

sexual harassment in a military setting than in other industries (Quick and McFadyen 2017).

The majority of workplace sexual harassment incidents are perpetrated against female employees by their male managers or co-workers (Quick and McFadyen 2017). Although women are generally exposed to more harassment than men, men and members of the LGBTQ community also experience workplace sexual harassment (McDonald 2012). At least some of this gender difference in workplace sexual harassment may be attributable to stigma that discourage men to report it (Kime 2014). The United States Equal Employment Opportunity Commission's (2012) data showed that the number of workplace sexual harassment complaints by men had increased 15.3% between 1997 and 2011. Quick and McFadyen (2017) surmised this rise may be due to reduced stigma around the topic of men's sexual harassment in recent years. Workplace sexual harassment due to one's sexual orientation is even more prevalent than harassment of women and men per se because there is no legal protection for LGBTQ workers in many countries, and the stigma on individuals' sexual orientation is greater gender discrimination (Ryan and Wessel 2012).

Antecedents of Workplace Sexual Harassment

Several theories posit that workplace sexual harassment occurs as a reaction to the traditional gender roles threat (Bates et al. 2006); as women gain status and power in the workplace, men harass them as a means of oppression. Bates et al. (2006) also suggest that workplace sexual harassment occurs between actors and targets in an organizational settings, and the act of harassment itself is heavily influenced by the social context.

Actor's Characteristics

Compared to the research on targets' characteristics, researchers have paid less attention to the role of actors' characteristics in understanding workplace sexual harassment (McDonald 2012). Men in higher power positions, such as managers, are frequently reported as actors of workplace sexual harassment. Walker (2014) also showed that former perpetrators engaged in subsequent workplace sexual harassment particularly when they had not been penalized for their previous actions. Actors' characteristics can also moderate the effect of organizational factors on sexual harassment. Dekker and Barling (1998) examined interaction of actors' characteristics with perceptions of company sanctions in predicting the sexual harassment at work. They found that workplace sexual harassment was more likely to occur when individuals with high levels of adversarial sexual beliefs, inappropriate sexual harassment beliefs, and low levels of perspective taking worked in organizations that provided weak rather than strong sanctions for sexual harassment.

Target's Characteristics

The power difference between perpetrators and victims is an important determinant of workplace sexual harassment. Previous studies show that young women and men were more likely to be harassed in the workplace (Chamberlain et al. 2008). Similarly, belonging to a minority group at work is another risk factor for victims. Disabled women, women working in environments dominated by men, homosexual workers, and workers who belonged to a minority race/ethnicity reported that they were victims of workplace sexual harassment more often than workers from the majority group (McDonald 2012). Employees at the intersection of two or more minority identities, such as both gay and a racial minority, were at an even higher risk of workplace sexual harassment than those of one minority identity (McDonald 2012).

Organizational Characteristics

Group level factors explain victimization better than individual factors because workplace sexual harassment affects members of certain groups more than individuals (Quick and McFadyen 2017). Research consistently showed that organizational climate of workplace sexual harassment tolerance was an important factor for predicting the occurrence of harassing behaviors (Willness et al. 2007). A lack of policies and procedures that penalized harassers (McDonald 2012) or a lack of management attention to formal and informal

complaints (i.e., whistle-blowing, Bates et al. 2006) meant harassers could get away with the results of their actions and feel empowered to do it again in the future. Similarly, gender-imbalanced organizations and organizations with high hierarchical structures also contributed to the problems and consequences of workplace sexual harassment (McDonald 2012; Quick and McFadyen 2017).

Outcomes of Workplace Sexual Harassment

Outcomes for Individuals

Experiencing workplace sexual harassment results in a wide array of occupational and mental health problems. In their meta-analysis, Hershcovis and Barling (2010) found that victims of workplace sexual harassment suffered from reduced job satisfaction, co-worker satisfaction, supervisor satisfaction, affective commitment, and psychological well-being, as well as increased turnover intention, job stress, and work withdrawal. Additionally, anxiety, depression, and post-traumatic stress disorder were commonly reported consequences of being a victim of sexual harassment at work (Willness et al. 2007). In another meta-analysis, Sojo et al. (2016) showed that rare but intense forms of workplace sexual harassment, such as sexual coercion and unwanted sexual attention, were as damaging as frequent but less intense forms of workplace sexual harassment, such as gender harassment. Lastly, the negative effects of workplace sexual harassment can go beyond organizational and individual effects to affect functioning in other role domains. For example, Dionisi and Barling (2015) demonstrated that the victims of workplace sexual harassment had difficulties in functioning romantic relationships because of their residual anger feelings from workplace sexual harassment.

Outcomes for Organizations

Workplace sexual harassment can cause damage to organizations both directly and indirectly. The direct costs include legal expenditures spent by organizations to resolve formal disputes around workplace sexual harassment. As sexual harassment is legally forbidden in almost 50 countries (McDonald 2012; Quick and McFadyen 2017), depending on the jurisdiction, organizations can be liable for not taking relevant measures to prevent workplace sexual harassment. The indirect costs of workplace sexual harassment go beyond legal costs to include how organizational functioning may be affected. Reduced employee motivation, morale, and performance can result in significant financial loss for employers. For example, a meta-analysis conducted by Willness et al. (2007) showed that the cost of workplace sexual harassment due to lost productivity was about $22,500 (USD) per person, and this number excluded the costs associated with litigation.

Preventing Workplace Sexual Harassment

Although intervention research aimed at reducing workplace sexual harassment is poorly developed at present, researchers emphasize the role of policy and training could lead to productive changes (e.g., McDonald et al. 2015). In their theoretical discussion, McDonald et al. (2015) examined workplace sexual harassment policies and training, as well as assessment of risk factors, as preventative intervention strategies. Effective policies contain clear statements of what constitutes workplace sexual harassment and articulate the grievance procedures, as well as penalties associated with harassment in a clear way (McDonald et al. 2015). It is not, however, enough to have such a policy. Hunt et al. (2010) underlined that workplace sexual harassment policies were ineffective unless they were enforced with "zero tolerance" principles.

Training is another method frequently used in organizations to reduce workplace sexual harassment. Training programs create awareness of the issue and increase the knowledge of what constitutes workplace sexual harassment. The interdisciplinary review conducted by Roehling and Huang (2018) showed that training could be an productive method in preventing workplace sexual harassment if it had a sound theoretical basis. Additionally, support from management is critical

in workplace sexual harassment training effectiveness (for a full review, please see Roehling and Huang 2018). Finally, workplace sexual harassment training programs can be delivered as a part of incoming employees' orientation. This strategy may be beneficial by delivering the message that workplace sexual harassment is considered a serious offense.

Conclusion

Workplace sexual harassment is a complex problem that affects women and men, minorities, and people from different sexual orientations. Basically, vulnerable workers are at a higher risk of being victims of sexual harassment at work. Workplace sexual harassment has serious consequences for both victims and organizations. Having appropriate policies and training that give a "zero tolerance" message can reduce the likelihood of WSH occurrences in workplaces.

To defeat workplace sexual violence, all members of the organizations must play an active role. Employees must be aware of the existing sexual harassment policies. If no policy exists, they must demand that their employers create, enact, and enforce a sexual harassment policy. Managers must actively monitor for sexual harassment behaviors in their workplaces, collecting data to support whether the policy is effective. They should follow the steps outlined in the policy when they observe others engaging in sexual harassment such as making sexist jokes. Observers of sexual harassment must also be held accountable for reporting the incidents of sexual harassment that they witness. Lastly, open-work culture is key in prevention. Both managers and colleagues must listen to the victims without judgment and encourage employees to report their experiences.

Workplace Violence: Active Shooter/Terrorist Threats

Kenneth W. O'Donnell

New York, NY, USA

Keywords
Active shooter · Workplace violence · Physical security

Definition

The Federal Bureau of Investigation (FBI 2019) defined an active shooter as one or more individuals actively engaged in killing or attempting to kill people in a populated area (p. 2). This definition excludes shootings that occur in the furtherance of various crimes, such as gang and drug activity.

Introduction

The Federal Bureau of Investigation (FBI 2018, 2019) identified 277 active shooter incidents in the USA from 2000 to 2018, most of which (44%) occurred in commerce locations (see ▶ "Workplace Violence: Past and Current Employees" in this encyclopedia). Approximately one-third of the shooters in business environments were current or former employees or had grievances against the businesses (FBI 2019; Silver et al. 2018). In addition to commerce areas, active shooter incidents have occurred in education environments (24%), healthcare facilities (4%), and government property (10%) which employ teachers, administrators, military, doctors, nurses, and various office staff (Blair and Schweit 2014; FBI 2018, 2019). In the majority of incidents (Silver et al. 2018), the 18-and-older active shooters (who were single, white, men) displayed multiple, disconcerting behaviors usually 25+ months prior to the shooting (56%).

Although the total numbers of incidents and casualties across 19 years (2000–2018) are high, the data shows fluctuation rather than a pattern of steady increase. From 2000 to 2008, there were 67 active shooter incidents resulting in 436 casualties, with a range of 1–14 incidents during this time span (FBI 2018). In contrast, from 2009 to 2016, there were 153 active shooter incidents resulting in 1115 casualties, with a range of 10–26 incidents (FBI 2018). The FBI (2018, 2019) reported the highest number of active shooter incidents for 2017 and 2018, with 30 active shooter incidents resulting in 729 casualties and 27 active shooter incidents resulting in 213 casualties, respectively.

Based on the data presented, it is essential that employees be prepared to address the issue of active shooter threats in their workplaces. The purpose of this entry was to help

organizations to consider an appropriate plan to help employees to prepare, mitigate, respond, and recover when faced with an active shooter situation. All organizations must have active shooter incident preparation in both their emergency management and business continuity plans. While all active shooter incidents cannot be prevented, analysis of active shooter incidents has shown that this violence can be prevented or mitigated through the application of strategies to assess and manage the threat. This entry is organized into the categories of preparation, response, and recovery as a means for presenting employers and managers with the steps that help employees when faced with potential or actual violence at work.

Preparation for Workplace Active Shooter Incidents

Many workplace active shooting incidents can be prevented or mitigated through proper planning and training. Planning for an active shooter incident should be part of an organization's larger emergency response and business continuity plans (see ► "Risk Analysis: National and International Standards" in this encyclopedia). Each plan should consist of a comprehensive scheme to address all aspects of an active shooter incident. Preparation should include training employees and staff in the recognition of potential workplace violence, implementing a broad array of processes for reporting and addressing individuals who are exhibiting the potential to engage in workplace violence, developing physical security measures to maximize workplace protection, and conducting regular drills to prepare staff for an active shooter incident. Organizations need to help their employees recognize when other employees may be prone to commit violence (see ► "Workplace Violence: Factors Contributing and/or Facilitating" in this encyclopedia).

Active shooters have exhibited clusters of externally identifiable behaviors that indicated a potential to engage in violence, initially through oral communication (95%) followed by physical actions (87%) (Silver et al. 2018). When there is a connection between active shooter and the attack site, the recognition and reporting of these clusters of behaviors can serve to prevent an active shooter incident. According to the FBI, there are 21 concerning behaviors demonstrated by past active shooters that had been recognized by others as occurring prior to the attacks (average of 4.7 behaviors). These behaviors have included indications of mental health issues (exhibited in 69% of cases), trouble with interpersonal interactions (exhibited in 59% of cases), and decline in the quality of the shooter's thinking and communications (exhibited in 54% of cases). Furthermore, 56% of active shooters exhibited what the study called "leakage," which was the shooter communicating with a third party their intent to harm someone. Other behaviors commonly observed in active shooters were poor work performance (46%), threats/confrontations (35%), anger (33%), and physical aggression (33%) (Silver et al. 2018).

As part of an organization's comprehensive plan to address an active shooter incident, employees should be trained to recognize clusters of behaviors indicative of an individual's likeliness to engage in violence and also be encouraged to report these behaviors to management. The FBI study on active shooters referenced above revealed in 40% of the cases, coworkers observed concerning behaviors of the active shooter prior to the attack (Silver et al. 2018). However, the employees either did not feel comfortable or did not believe they had a process to report these indicators to management. Employees may be reluctant to report the concerning behavior of coworkers because they do not want to be perceived to be undermining their peers. They often will wait until they are certain that an individual is serious about engaging in violence before reporting the individual. This is often too late. In order to maximize the prevention of active shooter attacks, organizations should create an environment where employees feel comfortable reporting potential indicators that an individual may engage in violence.

The creation of multiple pathways through which employees can report a colleague's behavior indicating a potential to engage in violence may increase the likelihood of obtaining this information in a timely manner. An environment should be created where employees feel

comfortable reporting concerning behavior of a coworker directly to a supervisor, knowing this information will be handled safely and discreetly. Workers may also be encouraged to relay information regarding suspicious behavior to their human resource or security departments. Some employees may not feel comfortable reporting suspicious behavior directly to another person. Therefore, organizations should have a process whereby employees can communicate their concern via e-mail or text message. Organizations can also employ drop boxes and tip hotlines to allow employees to report suspicious behavior while also maintaining their anonymity (Romano et al. 2011).

Physical Security in a Workplace

Proper facility management is instrumental in preventing or mitigating the effects of an active shooter (see ▶ "Physical Security: Best Practices" in this encyclopedia). The goal of physical security is to limit the ability of a shooter to access a site. Facilities managers should conduct a security assessment to determine the facility's vulnerability to an active shooter attack (see ▶ "Physical Security: Methods and Practices" in this encyclopedia). As part of this assessment, facilities managers should identify multiple evacuation routes in the event of an attack. These evacuation routes should be posted in conspicuous locations in a facility. This preparation should establish evacuation routes and procedures for individuals with special needs and disabilities (Alvarez et al. 2012).

Access controls, such as keys and security pass codes, should be instituted by management to limit access to a location to those permitted to be there. These credential-based systems can provide accurate accounting of those inside a facility. Site security, such as ensuring external doors and windows to a facility are locked from the outside, should be employed to further limit access to a facility. Ideally, closed-circuit television systems that provide views of an entire facility and can be accessed from a central command station should be installed (Alvarez et al. 2012).

In order to maximize communication in the event of an emergency, organizations should install a communications infrastructure that allows for facility-wide messaging. If the facility has elevators, the organization should install an elevator system that may be controlled or locked down from a central command station. An individual with knowledge of a facility's security procedure and floor plan should be designated to serve as a liaison with police and emergency responders in the event of an attack. Organizations should establish a central command station from which all security issues inside a facility can be addressed. If a facility has security guards, their patrols and patterns of operation should be varied to ensure that potential active shooters cannot circumvent a routine patrol. In order to maximize security, organizations should limit access to blueprints, floor plans, and other documents containing sensitive security information, but should make these documents available to law enforcement agents responding to an emergency (Alvarez et al. 2012).

Employee Training and Drills

Active shooter incidents should be addressed as part of an organization's comprehensive planning for workplace emergencies. Employee training for active shooter incidents should include familiarizing all employees with their expected response to an active shooter, the floor plan of the building, potential exits, and potential assembly areas outside the building for employees to regroup after evacuation during an incident. Ideally, this training will include both classroom training and drills where employees will practice their response to an active shooter and their evacuation from the facility. Outside organizations can be employed to conduct realistic active shooter drills to maximize employee training in the response to such incidents (Alvarez et al. 2012).

Response to an Active Shooter Incident

Both law enforcement personnel and private citizens have the potential to affect the outcome of an active shooter incident based upon their response. The first task of law enforcement when responding to an active shooter incident is to end the threat presented by the shooter in order to

reduce the casualty rate. Officers may have to pass injured victims as they proceed to confront the attacker. Once the shooter has been neutralized and the threat ended, the responders can address the injured and wounded. When arriving at the scene, responding officers usually do not know who the shooter is or whether he or she is acting alone. Therefore, employees must be sure to keep their hands empty and visible at all times. For their own safety, employees should follow the commands of the police and not run at them as officers enter the building or the room where the employee is located (Department of Homeland Security, DHS 2008).

Employees' responses to an active shooter in the workplace can be divided into three options – evacuate, hide, or fight – which they should do in that order (Alvarez et al. 2012). If there is an active shooter in the workplace, the primary response from employees should be to flee the scene if it is safe to do so. As their personal safety is of paramount concern, employees should not take the time to gather personal belongings. Instead they should leave all belongings behind and immediately flee. If they may safely do so, employees should warn others of the active shooter and instruct them to flee as well. After an employee has arrived in an area where they are safe, they should call 911 and notify the authorities of the shooter. 911 callers should describe each shooter in as much detail as possible, explain their locations, and describe the weapons the shooter may possess (DHS 2008).

When employees cannot safely flee the location, they should attempt to find a place to hide. Employees should hide in a location out of the shooter's view and stay as quiet as possible. They should silence all electronic devices and ensure they won't vibrate. They should also lock the doors and then barricade them with furniture, if possible. Employees should close any blinds or window shades and turn off the lights. The darkening of a room provides a tactical advantage for the employee as the shooter will have a difficult time seeing in the room from the outside and, if the shooter were to enter the room, the employee may have a momentary tactical advantage as the shooter's eyes have to adjust to the darkness (DHS 2008).

Fighting is a last resort in an active shooter scenario. When employees are in immediate danger and are unable to flee or hide, they should take every step to defend themselves to end the active shooter threat (DHS 2008). When engaging an attacker, employees should commit to their actions and act aggressively. They should remember that their attacker is trying to kill them and that they must aggressively act to end this threat to their lives. Whenever possible, employees should act together to ambush the shooter with makeshift weapons such as chairs, fire extinguishers, scissors, or whatever other weapons of opportunity may present themselves (DHS 2008).

Recovery from an Active Shooter Incident

The recovery process from an active shooter incident begins as soon as the emergency has ended. This process can be divided into initial and long-term recovery phases. The ultimate purpose of this process is to assist personnel in recovery and to restore organizations to their full functionality as soon as possible. The initial recovery process focuses on reestablishing safety and mitigating the effects of the incident. This process should begin immediately after an active shooter incident is completed. The establishment of active shooter response procedures and the conducting of drills as part of an organization's emergency planning process will ensure prompt and efficient implementation of the short-term recovery process (DHS 2017).

One of the first response tasks for an active shooter incident is to evacuate personnel to a safe area in an orderly fashion. As part of an organization's emergency planning, assembly areas for fire drills and other emergency incidents should be pre-designated. Staff and management should be trained in the location of these areas and the proper evacuation routes. Once evacuees have arrived at assembly areas, leadership should account for all evacuees and inform authorities

of those accounted for. Both management and the authorities should use the assembly area as a venue to address employees and inform them of updates and further steps in the recovery process. In order to ensure safety and accountability, evacuees should be instructed not to leave the assembly area until after they have been informed that it is safe to do so by authorities (DHS 2017). Management should ensure that individuals who have been injured or wounded during an incident are provided with emergency medical care from first responders at the assembly area. They should also ensure that individuals who require a greater degree of care than can be provided at the assembly area are transported to medical facilities (DHS 2017).

Organizational Crisis Communication and Media Response

It is imperative that organizations convey accurate and timely information regarding an active shooter incident (see ▶ "Emergency Management: Crisis communication" in this encyclopedia). As part of the active shooter response plan, organizations should ensure that crisis communication plans are in place and that there is a designated spokesperson to conduct all communications regarding the incident. The spokesperson chosen to conduct crisis communication should be well trained and briefed to provide responses to stakeholders, media, employees, and the public. Crisis communication should be closely coordinated with law enforcement to ensure it does not compromise the investigation or endanger safety (Stowell 2017). This communication should include information regarding the incident, contact information for emergency assistance, and other information that will help facilitate recovery. Employees who are not present at the scene of the incident should be provided with instructions regarding whether and when they are expected to report to work. As soon as possible, evacuees' families and friends should be told about their whereabouts and status. An organization's websites and social media accounts are effective means for conveying information. News media can also be utilized to communicate with the public (DHS 2017).

Reunification

Reunification of evacuees and survivors with their families and friends is an important aspect of the initial recovery process. Management should be prepared to accommodate the various needs of family members and friends and should implement a process to accommodate those who may rush to an incident scene. Friends and family members of survivors should be informed of assembly area locations as well as provided with estimates for when they can reunite with affected employees. In order to facilitate swift reunification, management should consider providing friends and family members with transportation to hospitals where survivors may have been taken (Department of Justice 2015).

Crisis Support in the Aftermath of an Incident

Management should consider setting up a Family Assistance Center (FAC) at the assembly areas if such assistance would be helpful in meeting the needs of affected employees. An FAC can be a formal or informal process to provide a wide array of assistance to survivors immediately after an incident. Assistance may include providing information about survivors relocated to hospitals or other assembly areas and the arranging for the reunification of survivors with their families and friends. FACs can also provide other necessary services such as temporary housing and meals and the coordination of legal and social services. A FAC can offer a confidential environment for families and friends of deceased victims to grieve in privacy (DHS 2017).

Retrieval of Personal Belongings

Procedures for workplace response to an active shooter incident emphasize that, if possible, employees should leave the scene immediately without taking time to gather personal belongings. Therefore, after the resolution of most incidents, many evacuees will want to retrieve personal

belongings left behind at the scene. Management should coordinate with law enforcement to set up a process for reclaiming personal property or notifying employees which items may be needed as evidence in the criminal investigation and legal proceedings (DHS 2017).

Long-Term Recovery

The objective of long-term recovery is to help employees return to a sense of normality and to return an organization to full functionality after an active shooter incident. The process of long-term recovery depends upon the specific organization as well as the circumstances of the active shooter incident (DHS 2017). Recovery should include employee assistance programs, grief counseling, reopening of the facility, holding memorials and anniversaries of the incident, and preparing employees for civil and criminal proceedings involving the active shooter incident.

Depending on the specifics of the active shooter attack, and the employee's role in an incident, individuals may suffer from an array of physical, psychological, and financial woes. One way that an organization can prepare to address the broad array of challenges that survivor employees may face is by establishing an employee assistance program (EAP). An EAP is a program that assists employees in addressing personal and work-related problems. This type of program can be beneficial in a myriad of ways to employees and may serve to facilitate the long-term recovery process. For example, an EAP can provide employees with access to grief counseling and assist with workers' compensation claims and other types of financial assistance. If an active shooter incident has resulted in injuries or deaths, an EAP can assist the affected individuals in applying for compensation for their medical expenses (DHS 2017).

Smaller organizations that do not have the resources of a large entity should consider utilizing outside community resources in order to provide this type of assistance. Thorough emergency planning should include exploring the available community resources that may assist in recovery (Stowell 2017).

The psychological impact of an active shooter incident on individuals can vary greatly for each person affected. Grief counseling can be an important tool to assist the recovery process for a broad spectrum of individuals impacted by an incident including survivors, their families, and friends. Proper planning for workplace emergencies should ensure that victims have access to grief counseling if needed (DHS2017).

Most organizations will seek to reopen their facilities as soon as possible after an active shooter incident has occurred. Proper emergency planning for an organization should include a business continuity plan to address the most efficient means to reestablish full operations as quickly as possible. This plan may include a variety of provisions that may be applicable depending on the specifics of an incident, including establishing alternate work locations and employing temporary staff. In seeking to reestablish operations, organizations should be aware that individuals recover from traumatic events at varying rates. Some individuals will recover quickly and return to work within days. Other will require more time or will not return to work at all. As much as possible, organizations should seek to accommodate the recovery process for employees. Organizations that have suffered an active shooter event should also conduct an after-action report to evaluate the response to the incident. This type of analysis can be helpful for both the affected organization and other organizations to establish best practices for active shooter events (DHS 2017).

Another way to aid in the process of grief is to hold anniversaries and memorial services to assist survivors and their friends and families address their traumatic experience and progress on the road to recovery. They can serve as an opportunity for survivors to reconnect with former coworkers. Organizations may consider facilitating memorial services as a way to help employees and their friends and families in the long-term recovery process (DHS 2017).

Finally, it is important to help employees with the legal aspects of the active shooting incident,

including both criminal and civil litigation. Comprehensive planning for active shooter incidents should include training for legal staff on the various civil and criminal law issues that may arise from such an attack. Management should ensure that the legal staff is prepared for requests for cooperation from authorities investigating and prosecuting criminal cases. The organization must also be aware that they may be the subject of various legal processes as part of a criminal investigation including subpoenas and search warrants. Furthermore, legal staff should be prepared to address potential civil litigation related to the incident (DHS 2017).

Organizations should be aware that employees may have to testify in various criminal or civil proceedings related to the active shooter incident as well as engage in preparation for their testimony. As part of their planning, management should consider a leave policy that accounts for employee absence during judicial proceedings. Furthermore, as part of the training for their response to an active shooter incident, employees should be made aware that they may be called to testify in various judicial proceedings (DHS 2017).

Conclusion

The number of active shooter incidents per year has more than doubled in the past 8 years when compared to the previous 7 years. A significant number of these incidents occur in a workplace. Active shooter incidents enact a toll that transcends the immediate numbers of those killed or wounded and can result in significant economic, psychological, and social costs. While all active shooter incidents cannot be prevented, proper preparation, response, and recovery can serve to prevent many attacks and mitigate the impact of those that do occur.

Workplace Violence: Assault

Duygu Biricik Gulseren and E. Kevin Kelloway

Keywords

Physical assault · Workplace violence · Homicide · Nonfatal workplace assault

Definition

Workplace assault refers to physically violent acts targeted at people at work or on duty with the intention of hurting them (LeBlanc and Kelloway 2002).

Introduction

For teachers, nurses, police, and many others, "bites, cuts, bruises are part of the job" ("5 most violent workplaces in Nova Scotia" 2014). Although this potential hazard may have been considered for many years as an unpreventable aspect of their employment, employees and their employers are now seeking ways to prevent workplace assaults. This entry aims to define, describe, and explain workplace assault.

Definitions of workplace assault used in different jurisdictions, such as by the National Institute for Occupational Safety and Health (NIOSH), includes threats of violent acts within the domain of workplace assault as well as physical violent acts themselves (Jenkins 1996). Some theorists have also suggested that assault can also be psychological or verbal (e.g., Gillespie et al. 2010); however, this view is increasingly rare. For example, Schat et al. (2006) operational definition of workplace assault included four categories of behaviors: (1) pushing, grabbing, and slapping; (2) kicking, biting, and hitting; (3) hitting or physically attempting to hit with an object; and (4) attacking with a weapon including a knife.

The lack of a consensus in the definition of workplace assault is a problem for three reasons. First, studies reporting prevalence rates are incomparable if they are based on different conceptual and operational definition of workplace assault. Second, victims of workplace assaults may have difficulty in identifying the problem; therefore, they may underreport incidents. Third, effective prevention strategies may differ depending on the adopted definition. For example, policies targeted to prevent verbal assault may be ineffective for situations where the problem of assault was conceptualized as purely physical acts. The best solution currently available is for researchers to use an operational definition (e.g., see Schat et al. 2006, above) in their reports which will allow everyone to understand what behaviors were included. In order to understand the complexity of workplace assault, the rest of the chapter will describe the literature regarding prevalence, sources, antecedents, outcomes, mediators, moderators, and prevention.

Prevalence of Workplace Assault

Nationally representative studies across the world report the incident rate of workplace assaults as 8% in Denmark (Hogh et al. 2003), 6% in the United States (Schat et al. 2006), 4% in Finland (Salminen 1997), and 1.5% in the United Kingdom (Cookson and Buckley 2012). Differences in national prevalence rates may reflect cultural features but may also reflect differences in sampling strategies and/or definitions of assault. For

example, Francis and Kelloway (2007) adopted the NIOSH's (1996) definition, which includes threats of violence and reported that 21% of their sample reported being victimized. Schat et al. (2006) excluded threats of violence and implemented a more rigorous sampling plan resulting in a prevalence rate of 6%.

Although workplace assault has a low base rate for the general population, workers belonging to specific occupational groups are exposed to assault more often than are others. Employees in protective services, such as police, military, and correctional workers, are at the highest risk (Schonfeld and Chang 2017). For these workers, violence is an expected part of the job as dealing with violent situations is literally part of the job description, and workers are typically provided with specific training and weapons in order to defend themselves and to stop potential assaults. However, the next highest risk group comprises individuals in occupations that work with the public to provide a service, such as nurses, teachers, retail workers, and bus drivers. In contrast to workers in protective services, service workers are rarely provided with specific training or means to defend themselves from assault.

LeBlanc and Kelloway (2002) suggested that occupational differences in the prevalence of assault were a function of specific occupational risk factors. They showed that such occupational risk factors (e.g., working alone, at night, around valuables, caring for other, or being the position of denying a service or enforcing rules) predicted workers' experience of violent assault and psychological aggression across occupations. In doing so, they demonstrated that the risk of violence was a foreseeable aspect of the job.

Sources of Workplace Assault

The United States Department of Labor and Occupational Safety and Health Administration's (OSHA 1996) classification of general workplace violence is based on the source and thus also applies to the topic of assault. The perpetrator of the assault can be (1) a stranger with a criminal intent such as a robber (i.e., type I violence), (2) a customer or client (i.e., type II violence), (3) a colleague or a past employee of the victim's employer (i.e., type III violence), or (4) someone from the victim's personal life, such as a family member (i.e., type IV violence). This classification is important because public-initiated and organization-initiated assaults have different outcomes (LeBlanc and Kelloway 2002). Type 1 and Type 2 public-initiated assaults are harder to prevent than Types 3 and 4 organizational-initiated assaults. Specifically, organizational policies developed to reduce or stop workplace assault perpetrated by insiders, but they are not capable, per se, of controlling the behaviors of customers and strangers.

Antecedents of Workplace Assault

Victim Characteristics

Victims of workplace assault share few demographic characteristics. Schat et al. (2006) showed that workers who are between 26 and 40 years old were more likely to be assaulted at work than those younger or older than this age range. Piquero et al. (2013) systematic review showed that, although male workers are more likely than female workers to be victims of a workplace assault, women reported assault incidents to the formal authorities more than men. Hogh and colleagues (2003) also noted that former victims of workplace assault were at risk for being assaulted again, perhaps because they did not report the initial incident. They attributed the positive relationship between past and future victimization to the worker's continuing tenure in a high-risk occupation.

Perpetrator Characteristics

Although the majority of the studies on workplace assault examined risk factors, studies have identified common characteristics across perpetrators. These included a history of violence, aggression and substance abuse, unstable self-esteem, negative affect, and trait anger (Barling et al. 2009). Although there is a small effect, some perpetrators suffer from mental illnesses (Barling et al. 2009). Lastly, client/customer stress due to an unfavorable interaction with the

worker or perpetrator's perceived aggression was also found to trigger workplace assaults (Piquero et al. 2013).

Work Characteristics

In general, dealing with the public, working in impoverished locations, handling money, or working in night shifts were primary risk factors for being a victim of an assault at work (Piquero et al. 2013; Schonfeld and Chang 2017). Studies conducted in the healthcare settings showed that working in the stressful environments, such as emergency rooms, psychiatric units, and addiction treatment facilities, increased the likelihood of being assaulted at work. LeBlanc and Kelloway (2002) identified 22 risk factors for violence. Their results showed that workers who handled weapons, exercised physical control over others, and dealt with individuals under medication were the most at risk for public-initiated assault (for the full list of risk factors, please review LeBlanc and Kelloway 2002). Lastly, working in stressful environments was associated with being a target of a workplace assault (Piquero et al. 2013).

Outcomes, Mediators, and Moderators of Workplace Assault

Although the prevalence rates of workplace assault are the lowest among all types of workplace aggression and violence, they have detrimental consequences on workers and their employers. These outcomes can be organized into two major categories: (1) health-related outcomes and (2) organizational outcomes. Health-related outcomes include impaired physical and psychological well-being indicators, such as increased somatic health complaints, burnout, depression, and low self-esteem (e.g., Hurrell et al. 1996; Mueller and Tschan 2011; Schat and Kelloway 2003). Organizational outcomes include undesirable consequences, such as financial burden to the organization, negative job-related affect, and turnover (Piquero et al. 2013; Schat and Kelloway 2003). Fear of future violence mediates the relationship between assault and its negative outcomes (Rogers and Kelloway 1997). Additionally, organizational support moderates the relationship between workplace violence and its negative outcomes such as that as organizational support increases, the link becomes weaker (Schat and Kelloway 2003).

Preventing Workplace Assault

The majority of intervention studies on workplace assault have been conducted in healthcare and retail settings. Workplace interventions aiming to prevent workplace violence are categorized in three groups: (1) environmental interventions, (2) organizational and administrative interventions, and (3) behavioral/interpersonal interventions. Environmental interventions, such as lighting the entrances or electronically controlled cash drop boxes, aim at changing the physical environment so that perpetrators are discouraged to attempt to assault. Organizational and administrative interventions involve policies and practices to protect workers from possible assaults. For example, many organizations have "zero tolerance policy" for workplace violence or harassment. This policy not only gives the message that assault is unwelcome in that workplace but also warns potential perpetrators about the consequences of their actions. Lastly, behavioral or interpersonal interventions include training programs to educate workers so that they know how to recognize and deal with assault. For example, conflict de-escalation techniques training programs teach employees how to recognize the cues of a potential assault and how to avoid it by taking preventative actions such as calming down the potential perpetrator. Studies have shown that environmental interventions are the most effective for preventing workplace assaults, but not all of research implement rigorous designs (Wassell 2009).

Conclusion

Workplace assault referring to a physical attack at work is a specific type of workplace violence. Compared to the verbal and psychological violence and aggression, workplace assaults have a lower occurrence rate. However, the

prevalence of this problem is highest in occupations involving those in protective or service-related employment. Assaulted employees suffer from ill health and produce poor organizational outcomes, mostly because of the fear of future violence against them. Based on the victim, perpetrator, and workplace characteristics, workplace assaults can be predicted.

There are several different ways to prevent workplace assaults, such as establishing environmental control methods, developing assault related policies, and training employees for possible assault scenarios. As a starting point, organizations should identify the primary sources of assault in their workplaces because the effectiveness of action can differ depending on the type of perpetrator (organizational/insider or public/outsider). There are several different types of workplace interventions on this topic. Among the intervention strategies, environmental control is known as the most effective in preventing workplace assaults by public perpetrators. In such cases, organizational decision-makers can consider redesigning their offices to reduce physical contact between their employees and the public. If Type III or Type IV violence is more common than the others, zero-tolerance policies and respectful work environment training have been effective for prevention.

Organizations must keep a record of incidents of assault that have occurred in their facilities. This is important, not only to identify the common sources of assault but also the employee and work characteristics that contribute to assault risk factors. Lastly, creating an open culture is essential to improve safety in the workplace. Employees should be encouraged to share their opinions about the effectiveness of the measures that have already been taken and to suggest what else they would like to see implemented to increase safety.

Workplace Violence: Factors Contributing and/or Facilitating

Lisa van Reemst
Department of Criminology, Erasmus School of Law, Erasmus University Rotterdam, Rotterdam, The Netherlands

Keywords

Workplace aggression · Contributing factors · Correlates

Definition

Workplace violence is "behaviour that a target wants to avoid, takes place in a work-related situation, and is potentially physically or psychologically damaging to the target" (Schat and Frone 2011).

Introduction

Workplace violence is considered a problem in many countries and among many occupational groups. Workplace violence refers to acts of aggression toward employees in a work-related context. Acts of aggression can, for example, include hitting, kicking, threatening, calling names, and bullying. The context of work can be the work location and during work hours but also outside these locations and hours, as long as there is a connection with work, such as a work relationship between persons. Workplace violence can occur in many variations. Incidents differ broadly in the occupational group it concerns, the type of workplace violence, and the type of relationship between victim and offender. First, workplace violence concerns all occupational groups, such as people at the office, service providers, and law enforcement employees. Second, regarding the type of workplace violence, workplace aggression can be physical (such as hitting and kicking) and psychological (such as calling names). Threats could be considered a form of psychological aggression, but some scholars consider this a separate type. In addition, specific forms of aggression are studied, such as sexual aggression, which can be psychological and physical. Third, the relationship between victim and offender can differ. Overall, there can be workplace violence between colleagues, between supervisor and subordinates, and between employee and citizen. This can be referred to as internal workplace aggression (initiated by people inside the work organization) or external workplace aggression (initiated by people outside the work organization). Often these variations co-occur. For example, looking at law enforcement officers (occupational group), they are most often exposed to external workplace violence (relationship between victim and offender), and while psychological aggression

is more common overall, they are more often exposed to physical violence than other occupational groups (type of aggression) (Van Reemst and Fischer 2016).

It is clear that workplace violence is, to some extent, not random (Barling et al. 2009). This means that there are characteristics that are related to workplace violence and that may contribute or facilitate workplace violence. This chapter will provide an overview of factors contributing to and facilitating workplace violence. These factors can be aspects of offender, victim, or context, as one can look at who the offenders are, who the victims are, or in which contexts workplace violence occurs. It is important to note that research about workplace violence is often based on a single survey, which means that is difficult to establish to what extent factors are actually facilitating or contributing to workplace violence, or more so a consequence of having experienced violence. It is thus important to interpret the results that will be described in this chapter with that in mind. The following paragraphs will first discuss offender characteristics contributing to workplace violence, victim characteristics, and then context characteristics. Each type of factor will be introduced by a real-world case of aggression against public service employees. Finally, possible variations in factors contributing to workplace violence will be discussed and a conclusion will be drawn.

Offender Factors

> A man who is caught during the day urinating in public. He runs away and spits the police officer who chases him in his face. When the officer catches him up, the man hits the officer with a fist against his jaw. After his arrest, the man bites in the hand of another police officer. (Bergman et al. 2013).

Offender characteristics can be related to workplace violence. Some people are more likely to offend than others, which, in general, is explained by being more driven by hostile or instrumental motives (reactive or proactive aggression) or by learning from previous social experiences (Penney et al. 2017). For example, in the described case, the man could, in general, have hostile tendencies or have the instrumental goal to escape from the police. Characteristics related to conducting workplace violence include sociodemographic, work, and psychological characteristics of this person. Regarding sociodemographic characteristics, aggressiveness in the workplace seems to be more often conducted by males than females. However, support for other associations with sociodemographic characteristics, such as with age, race, or socioeconomic status, is limited (Barling et al. 2009).

In addition, work characteristics could be factors related to conducting workplace violence. Both job and social stressors seem related to enacting workplace violence (Penney et al. 2017). Job stressors, for example, include conditions that interfere with task performance, such as insufficient time or assistance. Social stressors, for example, include perceived injustice (Penney et al. 2017). People who in general experience more job stressors and social stressors are more likely to enact workplace violence, possibly as a response to these stressors.

Furthermore, general psychological characteristics such as personality traits could be factors related to conducting workplace violence. Employees who have more propensity to experience negative affect, such as anger and sadness, seem more likely to conduct workplace (Barling et al. 2009, p. 676). In addition, employees with more trait anger and aggressiveness seem more likely to conduct workplace violence. Furthermore, employees with a history of aggression are more likely to conduct workplace violence again (Barling et al. 2009, p. 676), which could be related to described traits or social learning. Regarding offenders who are not employees, being under the influence of alcohol, drugs, or medicine seems to be related to offending an employee as a citizen (LeBlanc and Kelloway 2002). Offender characteristics, including sociodemographic, work, and psychological characteristics, are thus a group of factors that seem to contribute to workplace violence, particularly by

general tendencies and motivation to perform violence.

Victim Factors

> A young woman finds a man who is unconscious in the street and she calls an ambulance. It arrives quickly, but when the ambulance nurse succeeds in bringing the man to some level of consciousness, the nurse receives a head-butt. (Bergman et al. 2013).

Victim characteristics, in this case, characteristics of employees, can be related to exposure to workplace violence, due to the extent that possible victims are in contact with motivated offenders and lack guardianship and are suitable to become a victim (Cohen and Felson 1979). For example, employees could be more likely to be exposed to workplace violence if they are more often in contact with other people or, more specifically, people who tend to offend. Furthermore, employees could be more likely to be exposed to workplace violence if they lack safety precautions, such as social control or organizational policies, that limit workplace aggression. In addition to the situational opportunity to become a victim, there could also be a personal vulnerability to become a victim. For example, employees could be more likely to be exposed to workplace violence because they have characteristics that motivate others (more) to offend. This idea is based on the victim precipitation theory (Wolfgang 1958) which suggests that victims contribute to their own victimization. This theory has been criticized for blaming the victim, in this case the employee, but personal characteristics of victims could still be related, as has been shown in multiple studies. More specifically, some employees could act in ways, for example, violating norms or threatening others' identities, that, knowingly or unknowingly, results in being targeted (Aquino and Thau 2009, p. 723). Although the described case does not clarify the reason behind the head-butt, it is possible that the nurse, probably unknowingly, influenced this behavior of the patient. Based on studies about victim characteristics, three types of victim characteristics that may contribute to workplace violence will be distinguished: sociodemographic, work, and psychological characteristics.

Sociodemographic characteristics such as gender and age could be factors related to exposure to workplace violence. Overall, males seem to be more often exposed to aggression than females, and younger employees seem to be more often exposed to aggression at work than older employees. However, these are only small differences (according to a meta-analysis: Bowling and Beehr 2006). In addition, these are likely to be related to exposure to workplace violence due to other characteristics, such as job positions or behavior (Aquino and Thau 2009, p. 724; Hindelang et al. 1978).

Work characteristics such as the position in the organization and the feeling of having variability in and control over your job could be factors related to exposure to workplace violence (Aquino and Thau 2009). Overall, employees occupying lower positions in the organization seem to be more often exposed to workplace violence than employees in higher positions. Furthermore, employees who experience low variability in their job seem to be more often exposed to workplace violence than employees experience have more variability. Finally, employees who experience more role conflict and role ambiguity seem to be more often exposed to workplace aggression than employees with less role conflict and ambiguity (Aquino and Thau 2009; Bowling and Beehr 2006). Additionally, the job itself of employees is a factor that seems strongly related to exposure to workplace violence, but these will be described in the paragraph about contexts of workplace violence, as, in general, the job is a strong predictor of the context employees work in.

In addition, psychological characteristics (including behavior) such as affect and dominant or uncivil behavior could be factors related to exposure to workplace violence (Aquino and Thau 2009). Overall, employees who have more propensity to experience negative affect or are more emotional unstable seem to be more often

exposed to workplace violence, compared to employees who have less negative affect and are more emotionally stable. Finally, employees who have more dominant and uncivil behavior seem to be more often exposed to workplace violence. However, in some studies, it was found that also employees with low levels of dominance are more often exposed to workplace violence, that is, that both either relatively high or low levels seem related to more exposure to workplace violence (Aquino and Thau 2009). Victim characteristics, including sociodemographic, work, and psychological characteristics, are thus a group of factors, which seem to contribute to workplace violence, particularly by having either more situational exposure to workplace violence or by being more personally vulnerable to be confronted to workplace violence.

Context Factors

> Firefighters extinguish a fire during New Year's Eve. One of the emergency buildings of a physiotherapist is in flames. During the extinguishing activities, a boy who witnesses the fire shoots fireworks at the fire brigade. (Bergman et al. 2013).

Context factors are an additional group of factors which seem to contribute to workplace violence. First and foremost, the occupational group determines the type of work contexts employees are in and, thus, to what extent workplace violence occurs. Employees working in industry (Aquino and Thau 2009, p. 726) and law enforcement officers (Van Reemst and Fischer 2016) are at relatively high risk of exposure to workplace violence. One of the important related context characteristics is the amount and type of contact between the potential offender and victim. Workplace violence occurs more often in case employees spend more time together, as both co-workers or supervisor-subordinate dyads (Barling et al. 2009). Furthermore, employees who more often have contact with citizens are more often exposed to workplace violence than employees who have less contact with others (LeBlanc and Kelloway 2002). This contact could include physical or verbal contact and could include contact with various citizens, such as those who are more likely to offend (LeBlanc and Kelloway 2002). Therefore, also specific work days during which more contact occurs, such as New Year's Eve, could result in more risk of aggression (see described case).

In addition to the type of contact between people, the broader work context could be related to workplace violence. For example, leaders could fail to provide clear guidelines for what constitutes inappropriate conduct. This could result in workplace violence within the organization (Aquino and Thau 2009, p. 727). In general, a violence prevention climate seems to prevent workplace violence over time (Spector et al. 2015). This violence prevention climate includes management concerns, policies, and practices (and employees' perception on these topics) to cope with workplace violence in the organization (Spector et al. 2015). Context characteristics, including the extent and type of contact between potential offender and victim and policies regarding workplace violence, are thus a group of factors that seem to contribute to workplace violence, especially by having more situational exposure to workplace violence. This group of factors seems to be strongly determined by the occupational group employees work in.

Variations

It is important to note that different factors could be of influence on workplace violence, depending on the occupational group, relationship between offender and victim, and type of aggression. For example, whereas being under the influence of alcohol may contribute to workplace violence enacted by citizens, it is less likely to explain workplace violence enacted by employees, as use of alcohol is less common and accepted during work hours. Another example is that work characteristics seem stronger related to workplace violence among law enforcement officers than firefighters (Van Reemst and Fischer 2016), which was possibly explained by the larger variation within law enforcement officers in work situations and

exposure to workplace violence. Factors thus vary into what extent they contribute to workplace violence. Comparative research is scarce, but this is important to take into account when considering factors that contribute to workplace violence in specific contexts.

Conclusion

This chapter provided a general overview of factors contributing and facilitating workplace violence. Factors that were discussed were related to the (possible) offender, the victim, and the context and may relate to workplace violence through, for example, situational or personal vulnerability processes. In addition, it was highlighted that it may vary to what extent factors contribute to workplace violence. Taking these three groups of factors into account, workplace violence can be seen as an interaction between (possible) offender and (possible) victim in a certain context. As can be seen in the cases that were described at the beginning of each paragraph, often multiple contributing factors can be identified or suggested in a single incident. For example, in the first case of the man urinating in public, also the role of the behavior of the police officers and the context of arresting the man could be suggested to be contributing characteristics. This means that characteristics are likely to interact with each other. For example, an employee who enacted aggression before could particularly enact workplace violence if the other employee (victim) is emotionally unstable and little guidelines are available on workplace violence within the organization. Therefore, workplace violence could especially occur if factors related to higher motivation of offenders, less guardianship (such as guidelines), and more suitableness of the target are all present (cf. Cohen and Felson 1979). Important to note is that research on this topic, which factors contribute to workplace violence, is still ongoing. As has been implied in this chapter, more research is needed on how these characteristics are related to workplace violence over time (do all actually predict workplace violence, or are some a result of workplace violence – or both?), how characteristics interact, and how they vary between occupational groups, relationships between offender and victim, and types of aggression. In addition, more information is needed about to what extent this knowledge translates to effective interventions to reduce, prevent, or cope with workplace aggression.

Workplace Violence: Intimate Partner Violence

E. Kevin Kelloway
Department of Psychology, Saint Mary's University, Halifax, NS, Canada

Keywords
Active shooter · Domestic violence · Employee health risks · Stalking · Intimate partner harassment · Partner violence and work

Definition

As defined by the Centers for Disease Control and Prevention in the United States, intimate partner violence comprises threatened or actual violence or aggression (including sexual violence) directed at a current or former spouse or partner (c.f., Swanberg et al. 2006). Although this definition includes non-violent acts of aggression, more recently researchers have also used the term intimate partner aggression (LeBlanc et al. 2014) to refer to non-violent abuse within a current or former relationship.

Introduction

Intimate partner violence (IPV) can include same sex as well as heterosexual relationships. More commonly, intimate partner violence may also be referred to as domestic violence or as family violence. Although intimate partner violence originates outside of the workplace, it may spillover into the workplace or have consequences for employees' workplace behavior. As a result, intimate partner violence is a concern for workplace safety. This chapter reviews the incidence of IPV, consequences for both the individual and the organization, and possible interventions.

Prevalence of Intimate Partner Violence

Globally almost 30% of women report experiencing intimate partner violence at some point in their life (WHO 2013), with men experiencing intimate partner violence at a lower rate. In the United States, more than one in three women and one in four men are exposed to intimate partner violence at some point in their lives (Black et al. 2011). Intimate partners are identified as the perpetrator in approximately 1–3% of all workplace violence incidents (Duhart 2001).

As Swanberg et al. (2006) noted, prevalence rates may be underestimates as victims may not disclose or report on surveys. Moreover, official statistics may not record whether or not the perpetrator was a current or former partner. Despite these concerns, it is clear that intimate partner violence is a serious social problem in many parts of the world (WHO 2013) with substantial consequences for both individuals and organizations.

Individual Consequences of Intimate Partner Violence

There is a substantial body of literature that speaks to the significant mental and physical health

consequences of being a victim of intimate partner violence (Wathen et al. 2018). Of course, to the extent that the relationship involves physical violence, the risk of physical injury is clear and easy to understand. However, research has also identified a host of mental health disorders resulting from exposure to intimate partner violence. These include post-traumatic stress disorder (PTSD), eating disorders, sleep disorders, depression, and anxiety in addition to substance use disorders (Wathen et al. 2018). Victims of intimate partner violence may also experience a range of physical effects including chronic pain and cardiac disease as well as engaging in suicide attempts or self-harm.

As Wathen et al. (2018) note, there is an economic cost to intimate partner violence that accrues to both the victim and to society. Individuals may experience wage loss as a result of their inability to continue working while being victimized (see below), and these effects may be magnified through career interruptions and disrupted career progression for the individual exposed to intimate partner violence. Tolentino et al. (2017) found that women exposed to intimate partner violence were rated as engaging in lower levels of in-role (i.e., task) and extra-role (i.e., organizational citizenship) behaviors and, as a result, were seen as being less promotable by their supervisors than those actively engaged.

Organizational Consequences of Intimate Partner Violence

There are at least four ways in which intimate partner violence may affect, or manifest in, the workplace. First, consistent with the array of health effects previously discussed, victims of intimate partner violence may display impaired work performance or interpersonal interactions. Dimoff and Kelloway (in press), for example, found that individuals experiencing a crisis such as a mental health problem would display behavioral signs such as withdrawing from others in the workplace (e.g., not going for coffee or lunch, restricting interactions), expressions of emotional distress (e.g., crying or stating that they were stressed), engaging in extreme behaviors (e.g., theft, threats of self-harm, lack of personal hygiene), absenteeism or tardiness, and impaired quantity or quality of job performance. Consistent with this view, LeBlanc et al. (2014) reported that victims of intimate partner aggression demonstrated withdrawal at work (e.g., cognitive distraction, neglect of work), withdrawal from work (e.g., absenteeism, tardiness), and impaired job performance. Even when the intimate partner violence does not occur at the workplace, the signs of victimization may be evident in the workplace and significantly affect organizational outcomes such as attendance and job performance.

Second, intimate partner violence can occur at the workplace. For many individuals, work is a "social address." That is, partners or family members know where the person works and, often, his or her schedule. An individual intent on harming a partner may show up at that partner's workplace where they know he/she will be. Even when physical violence is not the intent, a confrontation, and attendant embarrassment of the partner, may be a form of intimate partner violence.

Third, and relatedly, a perpetrator may "stalk" his or her partner. Repeated phone calls, texts, and emails may be sent to disrupt the victim's workday. The perpetrator may wait outside the workplace for the victim to go to lunch or leave the workplace in order to provoke a confrontation. Simply being seen hanging around the workplace may be sufficient to provoke a feeling of being unsafe in the victim. Although this form of intimate partner violence does not involve the perpetrator entering the workplace, the clear intent of such actions is to disrupt the work performance of the victim.

Finally, the perpetrator can take action to interfere with the victim's ability to do, or get to, work. Disabling their car, hiding car keys, hiding clothes, or denying access to a home computer may all be ways of interfering with the victim's ability to work – again, without the perpetrator actually entering the workplace. Refusing to provide childcare may also interfere with the victim's ability to attend work as scheduled (Swanberg et al. 2006).

Interventions for Intimate Partner Violence

Intimate partner violence can, but usually does not, happen at the workplace and, as a result, may be seen as a "private" issue with which organizations should not be concerned. As the preceding review attests, nothing could be further from the truth – although intimate partner violence may not occur in the workplace, its effects manifest in the workplace and directly affect organizational functioning. Organizations have both a moral and a pragmatic rationale for taking action to assist individuals who are exposed to intimate partner violence. Organizational responses can include primary (i.e., providing specific security measures to assist employees), secondary (i.e., providing a supportive environment to help employees) and tertiary (i.e., providing access to mental health and other resources) interventions.

First, organizations can take specific actions to deal with the threat of intimate partner violence in the workplace and enhance the security of employees while at the workplace. Ensuring secure access to the worksite, escorting individuals to and from the parking lot before and after work, and screening calls are all actions that organizations can take to assist victims of intimate partner violence (Swanberg et al. 2007). Although these often emerge as responses to specific threats, a comprehensive workplace violence prevention plan should recognize the possibility, and take steps to mitigate the risk, of workplace violence resulting from intimate partner violence (Kelloway et al. 2017).

Second, a supportive environment may mitigate some of the negative workplace consequences of intimate partner violence. Tolentino et al. (2017), for example, found that organizational support moderated the effects of reduced job performance and organizational citizenship on supervisors' assessment of promotability. Organizations that make the effort to educate managers about intimate partner violence can create a culture in which being a victim is destigmatized, and the emphasis is placed on helping individuals in crisis rather than disciplining individuals for absenteeism, tardiness, or reduced job performance (for an analogous approach to mental health disorders, see Dimoff et al. 2016). Swanberg et al. (2007) found that listening with an open ear, sitting with a victim during a break, and providing individuals with increased flexibility (e.g., around schedules or workload) were all means of organizational support for individuals exposed to intimate partner violence.

Finally, organizations can also provide individuals exposed to intimate partner violence with access to resources to deal with specific issues. For example, Swanberg et al. (2007) found that organizations offered employees a referral through a counsellor or Employee Assistance Program for assistance with dealing with the strain of intimate partner violence. Although there is a lack of data supporting the effectiveness of Employee Assistance Programs for intimate partner violence, there is evidence suggesting that short-term psychotherapeutic interventions – particularly those based on cognitive behavioral therapy – can be of significant benefit to victims of intimate partner violence (Arroyo et al. 2017). Swanberg et al. (2007) reported that organizations could also provide information in the form of brochures or referrals to community-based organizations as a form of support to victims of intimate partner violence. Organizations that build links to these community resources are in a better position to both educate themselves about and offer support for individuals dealing with intimate partner violence.

Conclusion

Intimate partner violence – violence and aggression that occurs within a current or previous relationship – is a prevalent social phenomenon affecting more than a third of women and more than 25% of men in the United States. Individuals exposed to intimate partner violence can experience a wide range of physical and psychological disorders, many of which can last long after the exposure to violence has ended. Although not typically recognized as a workplace problem, it is clear that intimate partner violence (a) can manifest in the workplace by adversely affecting the ability of the victim to attend or focus on work and

(b) can occur in the workplace as perpetrators use the workplace as a social address for victims. Organizations have a role to play in addressing intimate partner violence by providing a supportive climate in the organization, by providing individuals with specific resources to deal with intimate partner violence, and by providing enhanced safety provisions for victims as part of a comprehensive workplace violence prevention program. Human resource policies that encourage individuals to report experiencing intimate partner violence allow organizations to provide supports to individuals as well as take steps to protect all individuals in the workplace.

Workplace violence · Workplace aggression · Counterproductive work behavior · Personality · Justice

Definition

Workplace violence can be defined as any employee behavior designed to harm (either physically or psychologically) an individual in the workplace (Day and Catano 2006; Dillon 2012).

Introduction

Roughly 50% of large American organizations (those with at least one thousand employees) reported an incident of workplace violence (United States Department of Labor, Bureau of Labor Statistics, and Survey of Workplace Violence Prevention 2005). In Canada, 21% of employees sampled reported experience some form of workplace violence, while 14% said that they experienced workplace violence within the last 2 years (Employment and Social Development Canada 2017). Workplace violence can encompass various types of deviant behaviors that produce harm physically or psychologically (Demir and Rodwell 2012), such as bullying (i.e., persistent acts of aggression toward an individual; Nielsen and Einarsen 2012), incivility (i.e., rude or discourteous behaviors with ambiguous intent; Leiter et al. 2011), and sexual harassment (unwelcomed sexual conduct or comment; Lee 2018). Aggression and violence are often used synonymously in the literature (Day and Catano 2006). This entry will treat these terms as synonyms but will maintain the original term(s) used in each source referenced.

Workplace violence (in any form) has a negative impact on both employees and the organization (Hogh and Viitasara 2005; Nielsen and Einarsen 2012). For example, coworker aggression has been negatively linked to emotional well-being and psychosomatic well-being as well as affective organizational commitment (LeBlanc and Kelloway 2002). In their systematic review, Hogh and Viitasara (2005) found several cognitive (e.g., trying to understand the event after the fact), emotional (e.g., anger, poor mental health, distress, fatigue, anxiety), and psychosomatic symptoms (e.g., tension) resulting from nonfatal workplace violence. Based on meta-analytic evidence, experiencing workplace bullying is associated with anxiety, depression, somatization, physical health problems, post-traumatic stress, burnout, and strain (Nielsen and Einarsen 2012). Bullying and sexual harassment are also positively related to psychological distress (Demir and Rodwell 2012). Organizational outcomes related to workplace bullying include increased intent to leave and absenteeism and decreased organizational commitment and job satisfaction (Demir and Rodwell 2012; Nielsen and Einarsen 2012).

Various antecedents of employee violence have been examined over the years; these include biological factors (e.g., gender), individual differences (i.e., personality traits), environmental or work-related factors (e.g., organizational justice, organizational culture), reactions to events (e.g., being a victim of bullying), and social issues (e.g., social norms; Day and Catano 2006; Trépanier et al. 2015). There is a fairly common (but unsupported) perception that layoffs can lead to aggression. Unemployment and layoffs can indeed cause anger and frustration that could lead to aggression (Catalano et al. 1997, 2002), but it is these emotions that influence violent behaviors, not the layoffs themselves (Barling et al. 2009). The majority of former employees do not take their anger out on the organization, despite potential feelings of bitterness (Fox and Levin 1994).

This chapter will briefly summarize the research on antecedents of workplace violence – both individual differences and environmental factors – committed by past and current employees (i.e., organizational insiders). However, it is important to note that the majority of workplace violence incidents (e.g., 90% of nonfatal workplace assaults; Peek-Asa and Howard 1999; 85% of workplace homicides; Sygnatur and Toscano 2000) are committed by organizational outsiders (e.g., customers, acquaintances, or those engaging in robberies or other crimes; Barling et al. 2009; McPhaul and Lipscomb 2004; Peek-Asa and Howard 1999) and are beyond the scope of this paper.

Individual Differences

The Big Five personality traits have been tied to aggressive work behaviors (Day and Catano 2006; Ones and Viswesvaran 2001). A meta-analysis by Grijalva and Newman (2015) found that agreeableness (i.e., kind, considerate, trusting) and conscientiousness (i.e., organized, responsible, thoughtful) were negatively correlated with measures of counterproductive work behaviors (CWB), while neuroticism (i.e., anxious, insecure) had a positive association with CWB. Agreeableness is most strongly associated with CWBs directed at individuals (CWB-I; e.g., Berry et al. 2007). Additionally, agreeableness has been shown to predict organizational retaliatory behavior (i.e., behaviors such as sabotage or assault due to perceived unfairness; Skarlicki et al. 1999). Spector and Zhou (2014) found that relational aggression was negatively related to agreeableness, conscientiousness, and emotional stability (the reverse of neuroticism). Agreeableness and honesty-humility (said to be the sixth personality trait; i.e., sincere and fair, lacking in greed and conceit; Lee and Ashton 2004) have been found to negatively predict antisocial behavior directed toward individuals (ASB-I), while extraversion seems to positively predict ASB-I (Lee et al. 2005). ASB is similar to counterproductive work behavior (CWB), when directed at individuals; there is some intent to harm those individuals.

Negative emotions and personality traits related to negative emotions have been linked to workplace aggression. Anger and frustration can lead an employee to engage in workplace violence (Fox and Spector 1999). Trait anger (i.e., a predisposition to anger and respond with hostility) is positively related to aggression directed toward both individuals and the organization (Hershcovis et al. 2007). The type A behavioral pattern (i.e., a set of characteristics including a proneness to irritability, impatience, competitiveness, and hostility) is also linked to workplace aggression (Baron et al. 1999). Somewhat similarly, Douglas and Martinko (2001) found that a hostile attribution style is positively corrected with both general workplace aggression and relational aggression.

Researchers have also looked at specific personality traits as predictors of workplace aggression. Negative affectivity (i.e., a tendency to experience general distress and aversive mood states such as anger and nervousness; Douglas and Martinko 2001) has been positively linked to interpersonal and organizational aggression (Hershcovis et al. 2007), overall workplace aggression (Douglas and Martinko 2001), and organizational retaliatory behavior (Skarlicki et al. 1999). Workplace aggression is negatively correlated with self-control, indicating that a lack of self-control can foster aggression (Douglas and Martinko 2001). Somewhat similarly, an external locus of control (i.e., a belief that one's source of control is due to external forces) is associated with overall behavioral reactions to frustrating conditions, specifically sabotage (Storms and Spector 1987).

Several other factors more internal to a person have been examined as possible antecedents. For instance, attitudes toward revenge are correlated with workplace aggression (Douglas and Martinko 2001). There is some mixed evidence that alcohol use may be linked to workplace violence (specifically directed at coworkers); however this tends to only hold under certain environmental factors (e.g., job insecurity or perceived injustice; Greenberg and Barling 1999). Past behavior is usually a good indication of future behavior; this statement holds for workplace violence (Day and Catano 2006). A history of aggression has been linked to engaging in workplace aggression as an adult (Greenberg and Barling 1999; Inness et al. 2005). In the next section, the role of environmental factors on employees' proneness to violence is explored.

Environmental Factors

Despite all the research on the personality determinants of workplace violence, meta-analytic

data show that workplace or environmental factors are more strongly correlated and explain significantly more variance in workplace aggression than do individual differences (Hershcovis et al. 2007; Inness et al. 2005). For instance, Inness, Barling, and Turner (2005) found that abusive supervision predicted workplace aggression above and beyond demographic variables, self-esteem, and history of aggression. Individual differences can actually moderate the relationship between situational factors and violent behaviors (Harris et al. 2010; Taylor and Kluemper 2012). For example, Colbert, Mount, Harter, Witt, and Barrick (2004) found that agreeableness moderated the relationship between perceived organizational support and interpersonal deviance such that the relationship was negative when agreeableness was low but positive when agreeableness was high.

There is a great deal of evidence on the link between perceived injustice and workplace violence (e.g., Baron et al. 1999; Inness et al. 2005). There are three general types of justice: procedural (i.e., perceived fairness of organizational decisions and procedures), distributive (i.e., perceived fairness of distributive outcomes), and interactional (i.e., perceived fairness of interpersonal treatment; Greenberg and Barling 1999). Using a meta-analysis, Hershcovis et al. (2007) found a correlation between distributive and procedural justice and interpersonal-targeted aggression and organizational aggression. Interpersonal justice, a type of interactional justice, is also related to workplace aggression (Dupré et al. 2006). Similarly, procedural justice has been found to negatively predict aggression toward a supervisor (Greenberg and Barling 1999). That said, individual differences (specifically negative affect and agreeableness) appear to moderate the relationship between perceived injustice and retaliatory behavior (Skarlicki et al. 1999).

Researchers have examined many organizational variables in relation to enacted aggression; these include job-related factors (e.g., workload; Baillien et al. 2011), supervisory-related factors (e.g., abusive supervision; Inness et al. 2005), interpersonal factor (e.g., conflict; Hauge et al. 2009), and job attitudes (e.g., job satisfaction; Hershcovis et al. 2007). Bentley, Cathley, Forsyth, and Tappin (2014) noted three workplace violence risk factors, namely, time pressure, workload, and communication. Greenberg and Barling (1999) found that workplace surveillance was positively related to aggression against one's supervisor. Interpersonal conflict, job dissatisfaction, and situational constraints have also been tied to interpersonal-targeted aggression and organizational aggression (Hershcovis et al. 2007). Other workplace variables linked to workplace aggression include (but are not limited to) role conflict, role overload, role ambiguity, work constraints, job autonomy, and perceived violence climate (Barling et al. 2009).

Organizational variables or environmental factors have also been tied to specific forms of workplace violence. For instance, instigated incivility (i.e., engaging in incivility) has been positively associated with organizational change, job insecurity, job demands, and experiencing incivility (from coworkers) and negatively associated with social support (from coworkers; Torkelson et al. 2016). Having a supervisor who engages in passive leadership (i.e., a lack of leadership behaviors) is linked to observed hostility (displayed by organizational members) and employees experiencing sexual harassment (Lee 2018).

Workload, job stress, lack of job autonomy, and uncivil climate are correlated with engaging in workplace bullying (Baillien et al. 2011; Goodboy et al. 2017; Taylor and Kluemper 2012). Job demands and resources have also been linked to bullying (Balducci et al. 2011). Specifically, workload and role conflict are positively associated with bullying, while decision authority, coworker support, and salary/promotion prospects are negatively associated with bullying (Balducci et al. 2011). Leader-member exchange (LMX; i.e., the quality and type of dyadic relationship exchanges between a subordinate and a supervisor; Ilies et al. 2007) has also been shown to negatively predict bullying (Porter et al. 2018). Based on meta-analytic data,

workplace harassment (i.e., interpersonal behavior meant to harm a target at work; simply another term for workplace bullying) is positively associated with role conflict, role ambiguity, role overload, and work constraints and negatively related to autonomy (Bowling and Beehr 2006).

Conclusion and Recommendations

Workplace violence has a negative impact on organizations and their employees. Various individual differences (such as personality traits) and situational factors (e.g., organizational injustice) are related to and can cause an employee to engage in aggressive behaviors at work. Often these individual differences and environmental factors interact. Despite the tendency to blame an (current or former) employee's predisposition to aggression, it is up to the organization to create and maintain an environment that will reduce the likelihood of its employees acting in this deviant manner. The use of multiple methods is more advisable than using a single preventative measure (Ta and Loomis 2007). Organizations should create policies and practices that outline acceptable behavior as well as working to instill an organizational culture with positive values (Bentley et al. 2014). Ta and Loomis (2007) advised considering hazards within the workforce, as well as community and industry characteristics, when designing or planning intervention efforts.

As a broad statement, organizations can make efforts to reduce job demands and increase job resources to decrease behaviors, such as bullying and interpersonal conflicts (Balducci et al. 2011). For instance, providing employees with role clarification could reduce a job demand (i.e., ambiguity; Bowling and Beehr 2006). Simply increasing communication among employees and throughout the organizational hierarchy may even reduce behaviors such as bullying (Bentley et al. 2014). Decreasing employee stress through reducing or removing workplace stressors can help lessen workplace harassment and bullying (Bowling and Beehr 2006). On a similar note, educating employees on ways to cope with stress and changing the way they appraise or react to stressors would also be beneficial.

Various types of training interventions can be used to help prevent workplace violence. For instance, bullying may be reduced by providing employees with conflict management training (Balducci et al. 2011). Leadership training (e.g., transformational or ethical leadership training) would be an effective intervention that can not only reduce workplace violence (Lee 2018) but have several other benefits (e.g., increase employee well-being and safety; McKee et al. 2018; von Thiele Schwarz et al. 2016). As passive leadership is associated with hostility and sexual harassment, leaders should be encouraged to take on an active role in their workplace and ensure they do not appear apathetic to harassing or aggressive behaviors (Lee 2018). Bystander interventions or awareness training for either managers or employees may also combat workplace violence, especially those behaviors that may be more ambiguous (Lee 2018; McDonald et al. 2016). For instance, sexual harassment training can increase participants' sensitivity to the type of behavior in question (Buckner et al. 2014).

When looking at minimizing the possibility of vengeful ex-employees, the approach is similar to reducing workplace violence perpetrated by current employees. Ensure that proper systems and procedures are in place, such as grievance, appeal, and harassment procedures (Fox and Levin 1994). Consider offering new former employees job-retraining options or opportunities (especially if these employees held a long tenure at the organization). In short, continue to treat these people with respect. Escorting newly fired employees from the building with security personnel will be less effective than simply showing that the organization still cares and respects their former employees (Fox and Levin 1994). That said, there are times when the risk of violence might be high (e.g., during labor disputes, disgruntled former employees following layoff or dismissal; Francis et al. 2006). In these circumstances heightened security precautions (e.g., restricting access to the workplace) might be prudent.

Definition

Workplace violence is "...any physical assault, threatening behavior, or verbal abuse occurring in the work setting" (NIOSH 1996). The Workplaces Respond resource center defines workplace violence as a violent threat or the act of violence targeting a person who is working. Violence can vary from intimidating language to a murder committed by anyone, including coworkers and management (Futures n.d.).

Sexual harassment is *unsolicited* sexually leaning conduct by someone in the workplace. Sexual harassment is also defined as a form of discrimination and therefore is a sex-related crime under Title VII of the Civil Rights Act of 1964 (Woerner and Oswald 1990).

Introduction

Sex-related workplace violence is linked to sexual harassment and other sex-related crimes. With criminal intent, sexual violence can be perpetrated by a coworker or an individual who has no reasonable association in the workplace. Often, the malefactor is committing a separate crime besides the violence. Causal crime examples include shoplifting, robbery, and trespassing. Rare and more serious sex-related crimes include rape (CDC 2013).

Customer/client or client-on-worker workplace sex-related violence involves clients and family members. This type of violence occurs frequently but is not limited to medical settings or medically induced situations (CDC 2013).

Worker-on-worker sex-related crimes, including sexual harassment, are referred to as lateral or horizontal violence and are among the most underreported crimes. Less than 16% of women report sex-related crimes to the police, according to the National Online Resource Center on Violence Against Women. Statistics from the US Department of Justice Bureau of Justice Statistics indicate that rape and sexual assault were reported to police 24% of the time. This is the fewest declared when contrasted with other workplace violence crimes (Futures n.d.). Worker-on-worker

violence often targets co-workers seen as "lower on the food chain," as with a supervisor to a subordinate (CDC 2013).

Personal relationship workplace violence is when the offender is in a personal relationship to a worker and violence happens at the workplace. With threats and violence, the consequences can also be against coworkers (CDC 2013). Workplace violence is connected to personal relationships in nearly one-fourth of instances. The typical situation involves a current or former romantic partner with workplace access who commits a sex-related crime of violence targeting an employee or customer (Futures n.d.).

Sexual violence is a workplace danger when anyone making contact with the workplace engages in sexually bullying or criminal behavior. The offender may be someone familiar or unfamiliar with the victim, such as a supervisor, co-worker, past or present dating partner, company client, or stranger. Sexual violence crimes vary from state to state but include rape, assault and battery, threats, sexual harassment, and unsolicited sexual touching (Futures 2017).

Osterburg and Ward (2013) point out that, due to a changing social environment, there are new types of sexual violence crimes in the workplace. Sexual exploitation of women, including the crime of rape, is facilitated by the growth of online technology and communication. Nearly all sex-related offenses require special attention and compassion, beginning with interviewing victims, witnesses, and even offenders require a high level of compassion and skill (Osterburg and Ward 2013).

Sexual harassment emerged as an issue when women entered the workplace, no longer working solely at home. Extensive studies disclose half of the women are sexually harassed while in their academic years or during their working career. Studies reveal that sexual harassment is terrifying, degrading, and at times physically violent. Harassment often continues for a long time and can cause acute psychological, health, and employment consequences. These issues have prompted social policy research and legislation (Fitzgerald 1993).

Criminal Intent with Sex-Related Workplace Violence

With criminal intent, as mentioned, sex-related crimes can be committed by someone with or without association with the workplace. The offender is often trying to carry out a separate crime concurrent with a sex-related workplace violence act. For example, a company parking garage mugging became a rape (CDC 2013). The leading cause of workplace homicides began with other criminal intent, according to a study by Tiesman et al. (2012).

Sex-Related Crimes

Sexual Assault

When she was finishing up her studies, Jenny Lee Corvo (2018) was directing a play and went to an associated hair stylist, the business owner. After his last stylist left, the man locked the salon door and began to cut Jenny's hair. When the owner brushed hair clippings off the salon cape, off Jenny's breasts, her fears and suspicions were confirmed. He held the cutting shears to her throat and proceeded to press against her and grope her private body areas. Gratified, he took payment for the haircut and let her out the door. Shook, Jenny tried to file a police report but was told she was not believable (Corvo 2018).

Rape

Mary St. Clair from Oakland, now a social worker, was raped when she was in the military by an officer. She did not report the crime out of shame and fear (Mosley et al. 2017).

Worker-on-Worker: Sex-Related Workplace Violence

The first sex-related worker-on-worker legal case was not until 10 years after passage of the Civil Rights Act, *Barnes v. Train* (1974). The plaintiff claimed she was terminated from her job for refusing to have an affair with her supervisor.

The case won on appeal after it was first dismissed (Woerner and Oswald 1990).

Haley Dillon et al. (2015) examined how differences between individuals are systemically related to different perceptions of sexual harassment. With its psychological and economic consequences, sex-related crimes are an important societal issue but difficult to define because of their subjective perception. Depending on one's gender and life history strategy (LHS), or background, sexual harassment resulted in significantly poorer life performance, including in the workplace. Those with a slow life history were more reticent and deeply affected (Dillon et al. 2015).

There are major, precedent legal cases concerning sex-related crime in the workplace. However, Paula McDonald et al. (2011) concluded through their research that there had been a reluctance in the workplace to seek avenues of redress and justice when violated by a sex-related crime. This is in spite of traditional and specific legal paths to follow when responding to sexual harassment. Using prevalence survey research, McDonald et al. (2011) reported that extra-legal strategies, the somewhat hidden but continual action of all organization types, do not tolerate reporting of worker-on-worker, sex-related crimes. Targets, or those who have been victimized by sexual harassment, are to use formal organizational grievance procedures or informal means to resist or redress sex-related crimes. Most targets do not officially report sex-related crimes due to reprisal fear or believing the grievance would not be taken seriously. Nonetheless, targets will seek assistance on their own or use informal, proactive, assertive options (McDonald et al. 2011).

Customer/Client: Sex-Related Workplace Violence

Kathleen McPhaul and Jane Lipscomb (2011) researched policy progress for the previous decade to document a state-wide mental health facility method to lower violence and violence threats. The overwhelming majority of workplace violence threats, including sex-related crimes, to caregivers and other health care workers, came from patients. Workplace violence comprises abuse, bullying, psychological violence, physical violence, racial aggravation, and sex-related crimes. Those interactions can include co-workers, supervisors, patients, families, visitors, and strangers (Cooper and Swanson 2002; International Council of Nurses 2000; McPhaul and Lipscomb 2011).

Personal Relationship: Sex-Related Workplace Violence

According to Barry Schwartz and Gary Srebrolow (2018), when working in close proximity to other employees, there can sometimes develop mutual attractions. This is the definition of the personal workplace relationship, which carries with it the danger of the relationship disrupting the workplace environment. For example, favoritism can be suspected by other employees or, if the relationship breaks down, there is tension and possibly a wrongful dismissal triggering a lawsuit and harassment complaint. The complaint is a sex-related crime if the offer and enticements connected to sexual favors, even if due to the personal relationship, are unwanted (Schwartz and Srebrolow 2018).

Workplace personal relationships can be a trigger for sex-related crimes of workplace violence from another employee. Even though little is known about the mind and mentality of the attacker who is also an employee, one reason is commonality at work (Holmes 1993).

Conclusion

In employment settings, there is a different risk assessment for sexual harassment and workplace violence, depending on management and its understanding of the types of sex-related violence to which the labor force, especially women, are likely to be subjected while working. Mitigating factors include the overall mental and physical health of workers and their well-being, morale, and sense of job satisfaction. All of these dynamics are also

directly related to organizational costs and productivity (Hatch-Maillette and Scalora 2002).

Sexual harassment laws, intended to reduce sex-related crimes, have produced significant changes in the workplace at the organization level. However, the implementation of sexual harassment laws has caused a backlash against management that initiates the regulations. According to research by Justine Tinkler (2013), sex-related workplace guidelines increase gender inequality attitudes between men and women, compelled by long-standing gender collaboration customs. Also, varying male and female hierarchical positions in the organization yielded unique but correlated concerns about status pressures caused by sexual harassment policies. Workplace regulations are intended to reduce inequality between social and gender groups. More studies are needed that analyze sex-related crime prevention laws and the social psychological processes they impact (Tinkler 2013).

Management perceptions and decision making in avoiding possible sex-related crimes in the workplace focus, particularly on gender. The female workforce usually has subjectively different circumstances when employed in traditional male workshops. Concerning sex-related crimes in the workplace, it is, therefore "mutually beneficial" for management and employees to assess the culture of safety and judgment of risk (Hatch-Maillette and Scalora 2002).
